APPLIED EPIDEMIOLOGY IN A GENERAL HOSPITAL

M. E. BARNES, M.D., DR.P.H.
IOWA CITY

Epidemiology has been defined by Hirsch¹ as "a science which will give, firstly, a picture of the occurrence, the distribution and the types of the diseases of mankind in distinct epochs of time and at various points of the earth's surface; and, secondly, will render an account of the relations of these diseases to the external conditions surrounding the individual and determining his manner of life."

As applied to a small community, such as a general hospital, it is with this second phase that epidemiology is concerned chiefly. Among its primary objectives become the exposing of the transmission paths of disease, or the recognition of conditions which may affect adversely the health of this particular community. Although such studies ordinarily are prompted only by the occurrence of actual cases of illness, there is no necessary reason why this should be so. If the epidemiologic approach is to have preventive application, potential hazards must be considered to be equal in importance to those which may have resulted in demonstrable actual damage. The mere fact that a fire has not occurred does not lessen the importance of searching for and eliminating fire hazards. The fact that no one has yet been killed does not warrant neglecting the hazards of accident. Unless we adopt the preventive point of view in epidemiology we will go along with smug satisfaction, thinking that all is well because no epidemic has occurred. Yet sporadic cases demonstrate as effectively as do epidemics that paths of transmission are open. By careful study of these cases we should be able to detect and to control the transmission paths, thus effectively preventing or limiting epidemic outbreaks.

ANCIENT METHODS

The epidemiologic possibilities become evident if we strip the veneer from the modern hospital and consider some of its basic features. Herodotus, speaking of ancient Babylon, said that the sick were carried to certain streets, where those who passed by inquired concerning their ailments. If any one had suffered a similar affliction, he told the sufferer what remedy or mode of treatment had proved beneficial in his own case. It was illegal for a visitor to refuse to listen to the recital of complaints as made by the patients. At

various temples of antiquity a somewhat similar procedure developed, except that the patients inquired of the deity to whom the temple was dedicated, or they slept in the presence of the sacred image. Later, special porticoes or pavilions within the temple area were provided where the sick were permitted to place their beds and where they were cared for by members of their own family. Eventually there appeared a group of individuals who specialized in knowledge concerning the relief of suffering and who were the forerunners of our medical profession of today.

In these ancient centers where the sick were concentrated the following features may be noted: (1) the patients, (2) the families of the patients acting as practical nurses, (3) the throngs of passers by, (4) the vehicular and animal traffic, e.g. ox-carts, beasts of burden, dogs and other small animals which passed to and fro along with the human traffic, (5) the food vendors, who carried viands kept warm by means of small charcoal burners, (6) the water carriers, usually slaves, who in jars or skins brought water for drinking or other purposes, and (7) the scavengers, usually slaves, who removed receptacles of excreta and other filth.

These various features are mentioned because, stated thus, one can see at once how much the patient was in contact with the entire community, the epidemiologic possibilities of such contact being quite obvious.

THE MODERN HOSPITAL

Yet these various features have their counterpart today. The modern hospital is but a hotel where sick folk may live and where facilities are provided for convenience in administering personal care and treatment. The street of antiquity has given place to the corridor along which today, as in ancient times, passes a constant stream of traffic, e.g. nurses, maids, orderlies, patients, physicians and interns, visitors. In one 900 bed state hospital studied, approximately 900 individuals are directly involved in its operation. The average daily census of patients is 742. The outpatients return to the various services at an average rate of 100 daily. The visitors average 400 daily. This hospital, in reality, is a small village with a population on any given day of well over 2,000 persons. Thirty-minute counts of pedestrian traffic were made over an interval of ten days, the counts being made at staggered periods which excluded the mealtime rush. In the main corridor along which the bulk of the traffic moves, individuals passed the observation point, during the time periods recorded, at a rate of more than 400 an hour.²

The traffic in the corridors of the patient floors is considerably less, but when one adds the activities of the 400 visitors to those of the personnel engaged in

the routine service of the hospital the traffic at any floor level is surprisingly heavy.

The vehicular traffic in hospital corridors is by no means negligible, e. g. patient carts, wheel chairs, laundry, diet and scrub carts. For the food vender of antiquity, we substitute the diet kitchen staff with its distribution carts. Water carriers and scavengers in the modern hospital have been supplanted only in part by plumbing systems. The direct handling of objectionable matter cannot be eliminated entirely. It is a curious fact also that the modern hospital preserves a physical similarity to the ancient one in its pattern. The individual rooms designed for the sickest patients open directly on the corridor, i. e. the street. The wards are but blind streets, separated from the thoroughfare by short hallways, oftentimes with service rooms on either side.

HEALTH HAZARDS

If this comparison with the ancient hospital is kept in mind, it is easy to visualize epidemiologic possibilities which otherwise tend to be obscured by the elaborateness of the modern institution. We must consider the general hospital to be a concentration point for individuals of lowered resistance. In either their present or past illnesses these patients often contribute to the hazards of their new environment. On the other hand they may be subjected at this concentration point to increased health hazards, which include a fair sampling of the transmissible diseases current in the community in which the hospital is situated. It must be remembered that all of the personnel engaged in the operating of a hospital have their homes in that community and participate in the various community activities. As a consequence, the separation between the hospital patients and the community is more imaginary than real. This is true of all hospitals, the difference lying chiefly in volume. The basic problems are common to all.

Entrance into a hospital is occasioned by the illness of the patient and, ordinarily, some element of urgency is involved. Under these conditions, except for cases of recognized communicable disease, epidemiology is usually most remote from the present interest of either the patient or the attending medical or surgical staff. The patient desires relief, not epidemiology. Thus, quite unawares and unintentionally the patient may introduce infections which interfere with the functions of the hospital even though they may not happen to result in important damage. The epidemic of scarlet fever and of hemolytic streptococcus infections in a maternity ward recently described by Diddle, Trussell and Plass³ was brought about by an expectant mother who was admitted to the maternity ward with an infection of the upper respiratory tract following exposure to scarlet fever in her own community. No one had any knowledge of this exposure until several weeks later, when the epidemiologic studies brought this point to light.

A child was brought to the orthopedic service, having been previously exposed at home to chickenpox. In the absence of knowledge of such exposure, he was placed in a small ward with the result that several cases of this disease developed among children in that group. In a distant ward two additional cases developed in children who possibly may have received their infection from him, although the channel through which such infection passed was not definitely proved. The development of eruptive disease in children encased in plaster casts complicates the problem of their care.

Repeatedly, children have been received who at the time were in the incubatory stage of measles. Prior knowledge of exposure to this disease does not always exist, but accurate histories relative to previous attacks enable one quickly to locate the susceptible, should a case of the disease develop. With such knowledge, immediate and effective measures are possible to prevent or to reduce the severity of the disease in the susceptible group.

On various occasions, individuals ill with other diseases have been admitted in ignorance of the fact that they were typhoid carriers. One need not dwell on the risk involved in handling such cases in the general wards, at least without adequate precautionary attention on the part of those immediately involved in their care. It would seem logical that all persons who have ever had typhoid and all patients with gallbladder disease should be studied to ascertain whether they are typhoid carriers.

It is common knowledge that in a general hospital which does not accept known cases of pulmonary tuberculosis the nurses and interns develop infections, as is indicated by the change in their reactions to the Mantoux test. As this change is not shared to a comparable degree by the students of the same age group in the same community, there is reason to suspect that patients with whom they are in contact may be spreaders of the disease. Obviously, patients with open tuberculosis who gain admittance to a general hospital bring their infection with them and add to the hazards of their new environment.

The hazards to patients in the new environment may be connected with the physical or routine aspects of the hospital. Recently, during the routine testing of the circulating ice water in a general hospital, evidence of contamination was found. Investigation disclosed that one of the services requiring cool water for washing some films had attached a rubber tube to the ice-water tap and led the water to the bottom of a small vat. With an open faucet valve, this constituted a perfect setup for back siphonage when and if a negative pressure developed in the water line. Evidently some back siphonage had taken place. Although in this particular instance no known damage resulted, numerous possibilities for back siphonage exist in most hospitals unless very painstaking search has been made to ensure their elimination. In one hospital it was necessary to install more than 600 vacuum breakers to eliminate potential back siphonage.⁴ Even so, the human element is difficult to control. In the laboratories, individuals who are unfamiliar with the possibilities of back siphonage are very likely to set up apparatus which creates the conditions for such development. In other instances, individuals may interfere with corrective devices. For example, an air breaker was installed on a bed pan washer to make back siphonage impossible. A student nurse who disliked the noise restored the original hazard by the liberal application of adhesive tape to the air breaker.

However, most of the hazards are connected with individuals rather than with mechanical devices. Godfrey and Pond⁵ recently reported a small epidemic of Flexner dysentery caused by contamination of the ice supply in a hospital. The situation which they described exists in most hospitals, and the hazards are increased

whenever ambulant patients are given access to the service rooms, as not infrequently is the case when they are rendering assistance to other patients.

Perhaps the center of greatest potential danger to any hospital is its otolaryngology service. Many of the operative cases there represent sequelae to some infectious disease. Hemolytic streptococci abound in the draining lesions of such patients. Many patients are children who, because of the difficulty of controlling them, may spread their infections to others. Scarlet fever, streptococcal sore throats and erysipelas are among the infections which result. In one instance investigated a series of five patients with scarlet fever and one with hemolytic streptococcus sore throat were shown to have had close contact with a patient suffering from discharging ears. When a culture was found positive and the patient was removed to isolation, further infections ceased.

That visitors may introduce infections to the patients whom they visit is an obvious possibility. The wonder is that such infections are not more numerous than they are. It is through the visitors and the employees that the patients share directly in the current health problems of the community. Recently a child in the orthopedic ward was visited by his father, who, as was ascertained later, was suffering from mumps at the time of his visit. In due time the child developed mumps, as did four other children with whom he was playing in the ward.

RESPONSIBILITY OF THE HOSPITAL

The general hospital, being a concentration point for the community illnesses, has also an opportunity and a responsibility to serve the community along the lines of epidemiology. A patient from another city entered the hospital suffering from amebic dysentery. In connection with his history, special attention was paid to epidemiologic aspects. It was found that he worked as a cook at one restaurant and his wife was employed at another. It became the duty of the hospital to acquaint the local health authorities with the situation in order that appropriate decisions might be made.

A woman who entered with chronic bacillary dysentery gave a history of working as a pastry cook in the dining service of a small college. In releasing such a patient to return to the same danger point, the hospital would assume a responsibility which it has no right to assume. The local health authorities should decide the conditions under which she may resume her occupation.

A woman entered the hospital for a small operation, received appropriate and successful treatment, and was discharged. On her history sheet, among the past diseases, appeared a record of typhoid suffered many years previously. Scant attention appears to have been paid to this item and, if any laboratory studies were made, it is not a matter of record. This is unfortunate, because within a few years she was proved to be the source from which an epidemic of typhoid developed. At that time there was reason to believe that she had been a carrier for many years. An epidemiologic study of the patient at the time of hospitalization might have resulted in averting the calamity.

Recently a group of five students from various parts of a university community entered the isolation hospital suffering from scarlet fever. A sixth student, daughter of a physician, was taken home by him because of the same disease. Through epidemiologic investigation of these cases it was learned that the one common activity was the eating of meals at a certain restaurant

within the incubation period of their disease. In gathering this information, a clue was secured as to two possible concealed cases among the employees. The local health officer, on being acquainted with the situation, confirmed the presence of the two affected employees and forced their isolation.

An epidemiologic service in a general hospital affords an opportunity for gaining experimental knowledge as to the mode of spread and practical methods of control of the various diseases studied. Propinquity does not necessarily mean effective exposure. Aerial transmission even within the same room is not so frequent as one might suppose. The studies of Rooks² and of MacDonald⁶ suggest that one might remain in a scarlet fever ward for as long as six hours before inhaling a single hemolytic streptococcus. Except when viruses are concerned, the direct implantation of the causative organisms appear usually to be a prerequisite for the spread of upper respiratory infections. By basing measures on this hypothesis it is possible oftentimes to effect a satisfactory degree of control without closing wards except for the time required for the investigation.

These brief illustrations typify what one may expect to find in any general hospital if epidemiologic study is made of the patients, personnel and hospital environment.

Responsibility for such studies should be centered in some one individual, who should have access to all services of the hospital, who will coordinate such investigations as may be necessary, and who will receive the fullest support from the heads of the departments concerned. It is feasible to report to him all cases of evident epidemiologic importance and to seek from him advice as to cases of dubious status. Responsibility should be placed on him to investigate the potential health hazards existing in the institution. When actual cases of communicable disease develop in the hospital, the affected wards should be closed as a matter of routine until his investigations have been made. His should be the responsibility of deciding on the measures needed to ensure that the hospital's functions may proceed safely and with the least possible delay. One of his duties should be to train the interns to recognize the epidemiologic possibilities in the situations faced and in the patients handled.

Centralization of responsibility is advisable because epidemiologic trails cross artificial boundaries in the hospital just as they do in larger communities. The individual case may develop in one ward but the trails may lead anywhere throughout the hospital or even into the surrounding community. Moreover, hospital epidemiology is quite complicated. The constant flow of visitors, the shifting of hospital personnel from ward to ward, the ingress and egress of patients tend to obscure the trails which a disease may have followed. However, in the absence of some great calamity we shall remain ignorant of the potential health hazards in these institutions until we make a serious attempt to uncover these trails. In particular instances we may fail to solve the epidemiologic problems. In fact, we may expect such failures to outnumber the successes. Nevertheless, in the effort to solve these problems we are certain to find potential transmission paths which need to be guarded, and we can work out procedures adapted to the existing situations which will reduce to the minimum the health hazards suggested in this discussion.

SUMMARY

As applied to a small community, a primary objective of epidemiology is the exposing of the transmission paths of disease or of conditions effecting adverse mass action in that community. Although such studies ordinarily are prompted by the occurrence of actual cases, there is no necessary reason why this should be so. If the epidemiologic approach is to have preventive application, potential hazards must be considered of epidemiologic importance whether or not resulting in demonstrable actual damage. The general hospital is a concentration point for individuals of lowered resistance. In either their present or past illnesses, these patients oftentimes contribute to the hazards of their new environment. On the other hand, in their lowered state of resistance they may be subjected at this concentration point (hospital) to increased health hazards representing a fair sampling of the diseases prevalent in the entire community.

Health hazards originate in patients, visitors, the hospital personnel or in the physical setup of a hospital. Because of their sporadic occurrence, attention usually is not directed to the avenues whereby infections are transferred. Thus these transmission paths remain undetected even though open. In a general hospital of moderate size the problems encountered justify placing the responsibility for current epidemiologic service on some definite staff member for the better protection of the patients, of the hospital personnel and of the community.

ABSTRACT OF DISCUSSION

DR. W. G. SMILLIE, New York: Dr. Barnes's conception of a modern hospital corridor as the arcade of a busy city is appropriate. The analogy applies also to certain other institutions, such as universities and large factories. These cohesive, closely knit units of our social fabric offer excellent opportunities for epidemiologic study. Dr. W. H. Welch defined epidemiology as "the study of the natural history of disease"; thus there is an epidemiology of cancer and of heart disease, as well as of dysentery and tuberculosis. There is an epidemiology of industrial accidents as well as an epidemiology of syphilis. Whenever groups of people are living and working in small, integrated social units, subjected to uniform environment, their activities and their contacts so controlled that they may be subjected to exact appraisal and analysis, conditions are ideal for epidemiologic study. It is generally believed that a successful epidemiologic study requires a massive accumulation of data, which will be appropriately analyzed and interpreted. The fallacy of this conception was emphasized years ago by Ezra Hunt, at the first meeting of the American Public Health Association in 1872, who said: "A great number of cases to observe is in some respects valuable, but confusion and difficulty of study sometimes arise from too great aggregation of disease under the extra artificial conditions of cities (contagious disease) hospitals, and so forth, and very much is to be learned from a few typical cases occurring under circumstances less complicated. There is often not so much to be learned by observing a very great number of cases as by an exhaustive searching into a few cases, all the facts of which are more within the grasp." In his paper, Dr. Barnes has applied the criteria of Ezra Hunt.

Rural Health Administration.—The establishment of local boards of health represents the first official attempt to attack rural health problems in America. These boards have been in existence for more than one hundred years and in some rural areas they still function in very much the same manner as they have through the generations. The first local boards of health were established in Massachusetts in 1797. Connecticut followed in 1805.—Smillie, Wilson G.: *Public Health Administration in the United States*, New York, Macmillan Company, 1940.

PERFORATING GUN SHOT WOUNDS
OF THE ABDOMEN

AN ANALYTIC STUDY AND STATISTICAL REVIEW
OF TWO HUNDRED AND NINETY-TWO CASES

ELKIN L. RIPPY, M.D.

NASHVILLE, TENN.

Injuries and deaths resulting from gun shot wounds should be of vital interest to every one, since at the present time over half of the world is engaged in war and the peace of the rest of the world hangs by a thread. Perforating gun shot wounds of the abdomen should be of special interest to the general surgeon because the mortality rate has not been greatly lowered during the past twenty-five years and, therefore, this type of injury remains the most effective method of killing. Although surgical judgment and technic have improved, there has also been a corresponding increase of 20 per cent in the velocity of the bullet, which causes more damage to the abdominal organs. Fortunately, the incidence in civil practice is rare.

MATERIAL REVIEWED

This paper is based on a study of 292 cases of gun shot wounds of the abdomen with visceral perforations which occurred in Nashville, Tenn., during the period of 1923-1939. Of the twenty-four cases in which exploration was not done there were twenty-three deaths, or a mortality of 95.8 per cent. However, of 268 cases in which exploration was done there were 166 deaths, or a mortality of 61.9 per cent. This is quite high, but not far out of line with the reports of other surgeons reporting on a large series from general hospitals. It should be emphasized that only those cases were considered in which there were visceral perforations, whereas in most reviews cases are included in which the abdominal wall and peritoneum had been penetrated without visceral perforation. By including the cases without perforation the mortality would obviously be lower.

After studying the peace time reviews of cases that occurred during approximately the same period as covered by this review, and including only cases in which a viscus was perforated, and further including only the series in which the total number of cases was over 100, it was discouraging to discover that the operative mortality remains approximately 60 per cent. This was found to be true of the report of Taylor¹ of Indianapolis, Loria² of New Orleans, Mason³ of Birmingham, Ala., and Oberhelman and LeCount⁴ of Chicago, as well as the combined statistics of men reporting cases from Charity Hospital of New Orleans. One of the few exceptions to this is the report of Billings and Walkling,⁵ reporting 114 cases from Philadelphia with an operative mortality of 48.2 per cent. This is the only large series reviewed showing an operative mortality below 50 per cent. There were

found several small series of selected cases in which the mortality was below 50 per cent, but these could not be called representative of the true state of affairs. For example, a review of the operative mortality at the Nashville General Hospital for one year gave only 35.7 per cent.

Since the mortality still remains high, we have tabulated and attempted to evaluate the results in this study, to the end that some conclusion may be reached as to the lack of progress in lowering the mortality.

The type of weapon used, the age, sex, color of the patients, and the viscera or vessels perforated are all factors influencing the mortality which are beyond the surgeon's control. However, the promptness of preparation for operation, choice of anesthetic, operative technic, length of procedure and preoperative and postoperative management are factors in the lowering of mortality that are under the surgeon's control.

INCIDENCE

The incidence of gun shot wounds of the abdomen is rare in most parts of the country as revealed by the statistics from the Metropolitan Life Insurance Company. However, in Nashville it ranks as one of the most frequent emergencies seen in the charity hospitals and occurs with six times the frequency of ruptured gastric ulcer and twice the frequency of ruptured duodenal ulcer. The number of cases has steadily increased in Nashville during the past fifteen years, and by grouping the cases in five year periods and comparing them, it was found that the incidence has increased 100 per cent, although during this period the population of the city has increased only 16 per cent (table 1).

It has been repeatedly said that the smaller the caliber of the rifle or pistol the lower the mortality, and this fact is borne out in the present review. Seventeen persons were shot with a 0.22 caliber rifle with a mortality of 41.1 per cent, 241 shot with pistols with a mortality of 63.4 per

cent, and thirty-four injured by shot guns with a mortality of 85.2 per cent. The reason for the high mortality from shot guns was that most of these cases were attempted murder, shot at close range and tearing large holes in the viscus, making most of the wounds almost impossible to repair (table 2).

AGE, SEX, COLOR

The youngest person was 5 years of age and the oldest was 80 years of age, but the greatest number, 125, or 42.4 per cent, occurred between the ages of

21 and 30. It was interesting to note that the mortality increased steadily with the decades of life, the lowest rate, 50 per cent, occurred in the age group of 1-10 and the highest rate of 85.7 per cent between the ages of 61 and 70 (table 3). The lower mortality rate in the younger group could be accounted for by the fact that most of the accidental injuries from 0.22 rifles

Colored female.....	36	21	15	58.3
White female.....	13	9	4	69.2

were in this group. Also the increased stamina of youth probably enhanced the chances of recovery.

Similar to other reports, the greatest number of patients in our series were males, 243, or 83.2 per cent; forty-nine, or 16.8 per cent, were females. Ranked as to frequency there were 150 colored males, or 51.3 per cent, ninety-three white males, or 31.9 per cent, thirty-six colored females, or 12.4 per cent, and thirteen white females, or 4.4 per cent (table 4). It has been believed that owing to the well developed muscles of the average colored person as contrasted with white persons there is a lower mortality in the colored as the result of the fact that the bullet might be partly spent before it entered the abdominal cavity and was therefore not capable of doing as much damage. This assumption seems to have been supported in this review, as the mortality in the colored race was 62.3 per cent as contrasted with 68.8 per cent for the white race (table 5).

It was shown also that females tolerated abdominal injuries resulting from gun shot fire better than males, and the mortality in the female was 61.2 as against 65.4 per cent for the male.

ADVANTAGE OF EARLY OPERATION

The improvement in transportation has made it possible for the injured to arrive at the hospital within a short period of time, but it seems that there is still too much delay in the beginning of the laparotomy. This, in part, may be due to the fact that most of our cases came at night or on holidays when the efficiency of the personnel of the hospital was at the lowest ebb. Another factor that might have contributed to the delay was that the patient was usually first seen by an inexperienced intern who might not have fully appreciated the seriousness of the condition and might have underestimated the degree of shock.

Preliminary x-ray examinations may be of value in the determination of the possibility of questionable entrance into the abdominal cavity, but as a routine procedure this should be discouraged because of the imposed preoperative delay and the added moving and handling of patients, many of whom are in an extreme

degree of shock. The statistics in this review show that, the earlier the patient was operated on, the greater the chance of recovery. From an analysis of the records of 112 patients who were first seen in the outpatient department of one of the hospitals, it was found that of those in a serious condition and dying within six

Over 9.....	10	6	4	60.0

hours of admittance to the hospital 30.7 per cent had been given x-ray examinations. I believe that this loss of time necessary for preliminary x-ray examination contributed more to the mortality of these patients than was justified by the diagnostic aid to the surgeon at the time of exploration, for the experienced surgeon regularly examines all of the intestinal tract.

Accurate data were kept on the length of time elapsing from the receipt of injury to the beginning of the operation and showed convincingly the advantage of early operation; for in those operated on within two hours the mortality was 60 per cent and the fatality rate increased steadily as time elapsed until with an interval of from six to nine hours the mortality was 71.4 per cent (table 6). After nine hours the mortality again was lowered to 60 per cent. Apparently this was due to the fact that large hemorrhage had not occurred in many of these cases.

AMOUNT OF HEMORRHAGE

It has been shown by Mason, by Loria⁶ and by this study that the amount of hemorrhage is the greatest single factor in the determination of the mortality. Therefore, when a patient is seen in shock following gun shot injury of the abdomen it is safest to assume that this shock is due to actual blood loss and prepare the patient for exploration as soon as the blood pressure has been raised to a level at which a laparotomy can be fairly safely performed. However, this opinion is not shared by all and there have arisen two schools of thought in the management of such patients, the first, as already advocated, treating the patient for shock in the operating room and performing exploration at the earliest possible moment to check active hemorrhage, the second assuming that the shock is primary and deferring operation for several hours while combating shock.

The presence of blood in the abdominal cavity was recorded in 222 cases in the series under analysis. The amount of blood was estimated by the surgeon as large, moderate or small. We have used the same classification as other men have used; namely, large

hemorrhage group 1,000 cc. or more, moderate hemorrhage from 500 to 1,000 cc., small hemorrhage 500 cc. or less.

There were 112 cases in the large hemorrhage group, with a mortality of 83.9 per cent (table 7).

In the moderate hemorrhage group there were forty-eight cases with a mortality of 60.4 per cent and sixty-two cases in the small hemorrhage group with a mortality of 43.5 per cent. This study shows convincingly that the amount of hemorrhage is the greatest individual factor in the mortality irrespective of the organ damaged.

VALUE OF TRANSFUSION

It was a difficult task to find suitable donors in a short period of time, as there were no available funds for the use of professional donors at the Charity Hospitals, where the greatest number of these cases occurred. However, ninety-nine (30.4 per cent) of the 292 patients were given transfusions for from one to ten times, which affords a sufficient number of cases to study the value of this procedure.

In the large hemorrhage group forty-seven, or 41.9 per cent, of the total group were given transfusions with thirty-five deaths, or a mortality of 74.4 per cent. In contrast to this there were the sixty-five cases in which transfusions were not given, with a mortality of 90.7 per cent (table 8). In this group the mortality was lowered 16.3 per cent by transfusion.

In the moderate hemorrhage group thirty patients were given transfusions, or 62.5 per cent of the total, with nineteen deaths, or a mortality of 63.3 per cent; but eighteen patients were not given transfusions, with ten deaths, or a mortality of 55.5 per cent. In this group there was no lowering of the mortality.

In the small hemorrhage group twenty-two, or 35.4 per cent, were given transfusions, with eight deaths, or a mortality of 36.3 per cent, as against forty not given transfusions, with nineteen deaths, or 47.5 per cent. In this group the mortality was lowered 11.2 per cent.

TABLE 7.—Amount of Hemorrhage, with Mortality

Amount	Total	Died	Lived	Mortality
Large.....	112	94	18	83.9
Moderate.....	48	29	19	60.4
Small.....	62	27	35	43.5

TABLE 8.—Study of the Value of Transfusion

Group	Transfused			Not Transfused		
	Number	Died	Mortality	Number	Died	Mortality
Large.....	47	35	74.4	65	59	90.7
Moderate.....	30	19	63.3	18	10	55.5
Small.....	22	8	36.3	40	19	47.5
Total.....	99	62	63.5	123	88	71.5

In the total it was found that of the ninety-nine given transfusions the mortality was 63.5 per cent; in the 123 not given transfusions the mortality was 71.5 per cent. Thus in those who received blood the mortality was 8 per cent lower than in those not receiving blood.

ORGANS PERFORATED

Next to hemorrhage the most important factor in the death rate is the organ or organs perforated. The mortality increases when more than one organ is per-

6. Loria, F. L.: The Influence of Hemorrhage in Abdominal Gun Shot Injuries, *Ann. Surg.* 96: 169-178 (Aug.) 1932.

forated, as the number of holes and degree of destruction of the organs increase and as the site of perforation descends in the intestinal tract. The lowest mortality was in perforation of the liver, 44.4 per cent, and then the mortality steadily increased as the stomach, small intestine and large intestine were reached. The mortality of perforation of the large intestine was 65.9 per cent (table 9).

The small intestine was perforated most often, 136 cases with an average number of holes of 6.2, the large intestine next with eighty-nine cases giving an average number of holes of 2.5, and last the stomach with sixty-eight cases giving an average number of holes of 2.05.

OPERATIVE PROCEDURE

Simple closure is the best procedure for perforation whenever possible, for any attempt at resection is associated with high mortality. However, this becomes necessary at times when the blood supply to the intestine is destroyed or a considerable portion of the intestine is shot away. There were thirty-three cases in which a portion of the intestine was resected varying from several inches to several feet with twenty-seven deaths, or a mortality of 81.8 per cent. In case of

TABLE 9.—Mortality of Perforation of Different Organs

Organ	Single Organ			Two or More Organs		
	Total	Died	Mortality	Total	Died	Mortality

Bladder.....	2	12	9	75.0
Pancreas.....	3	1	33.0
Large vessels...	4	4	100.0

severe damage to the movable portion of the large intestine it is advisable to bring the damaged portion outside the abdominal cavity rather than to try and do a resection. Six splenectomies with five deaths, or a mortality of 83⅓ per cent, were performed. There were also thirty-three cases with associated chest and abdominal injuries giving twenty-eight, or 81.7 per cent, mortality.

ANESTHETIC

Ether was the anesthetic of choice, as it gave the required relaxation not associated with very much shock. Spinal anesthesia was only occasionally used, as it causes too much drop in the blood pressure, which is often already at a dangerously low level. Another practical objection to spinal anesthesia is the fact that it may cause contraction of the intestine, forcing more of the intestinal contents out into the abdominal cavity. Local and gas anesthesia did not give the proper relaxation and made it necessary for the operator to fight the intestine, causing further shock and squeezing more material out into the peritoneal cavity. Ether was used in 244 cases, with a mortality of 61 per cent; in the remaining twenty-four cases in which local, gas or spinal anesthesia was used the clinical notes were insufficient for accurate statistical analysis.

Paradoxical as it may seem, the mortality decreased in inverse proportion to the length of the operation (table 10).

In the short operations of less than thirty minutes the mortality was 77.7 per cent, and the mortality

was gradually reduced as the length of the anesthetic increased until the lowest rate was between ninety-one and 120 minutes, when the mortality was 54 per cent. After two hours the mortality again increased and this probably can be explained by the fact that the operator was exceedingly slow or there was a great deal of

TABLE 10.—Length of Operation, with Mortality

Time	Number	Died	Lived	Mortality
0 - 30 minutes.....	9	7	2	77.7
31 - 60 minutes.....	84	53	31	63.0
61 - 90 minutes.....	80	48	32	60.0
91 - 120 minutes.....	50	27	23	54.0
121 - 180 minutes.....	21	14	7	66.6

damage to repair. The high mortality in the operative group requiring less than one hour can be explained by the fact that, first, in the most serious cases death occurred within thirty or forty minutes; in nineteen of the operative cases, death occurred on the operating table. Secondly, the hasty operator is more likely to overlook perforations, and it is not of much value racing against time to close eight or ten perforations and leave one not closed. In the twelve autopsies performed in cases in which the operations had been completed, overlooked perforations were found in six, or 50 per cent, and four of these six, or 66⅔ per cent, were found in operations requiring less than one hour. It should be emphasized that slowness is not a virtue, but in an attempt to secure speed the operator should not sacrifice thoroughness.

CAUSE OF DEATH

In the 189 cases in which death occurred, the time elapsed between the operation and death varied from a few minutes on the table to ninety-three days. The vast majority of patients died within twenty-four hours. It cannot be determined accurately whether a patient dies of shock and hemorrhage and when peritonitis supervenes, and there is undoubtedly an overlapping and combination of all these factors. I have arbitrarily classed those dying within twenty-four hours as dying of shock and hemorrhage, and those after twenty-four hours as dying of peritonitis or some other cause than shock (table 11).

Table 11 shows that in 59.8 per cent of the fatal cases the cause of death was shock and hemorrhage

TABLE 11.—Cause of Death

Intestinal obstruction.....	3	1.5

and in 29.6 per cent peritonitis. Only a small percentage of deaths were due to other causes. It is interesting to note that there were no records of any deaths from tetanus and only five from gas bacillus infection. In the last three years there have been no deaths due to gas bacillus infection. Shortly after sulfanilamide was given to the medical profession in this country it became my routine practice to use this agent in large doses intraperitoneally at the time of operation. This was supplemented by parenteral use of sulfanilamide

postoperatively. The prompt use of this drug was, I believe, undoubtedly of considerable value in combating infection.

Of the 103 patients who lived, the period of hospitalization varied from eight to 105 days, the average length of time being 29.1 days.

SUMMARY

1. Two hundred and ninety-two cases of gun shot wounds of the abdomen with visceral perforations were studied.
2. The smaller the caliber of the pistol or rifle, the lower was the mortality.
3. The mortality increased steadily with the decades of life.
4. The greatest number of patients were males, 83.2 per cent; 60.2 were Negroes.
5. The statistics in this review showed that, the earlier the patient was operated on, the greater was the chance for recovery.
6. The amount of hemorrhage is the greatest single factor in the mortality irrespective of organs damaged.
7. Ninety-nine patients were given transfusions and in this group apparently the mortality was lowered 8 per cent.
8. The mortality increases when more than one organ is perforated, as the number of holes and degree of destruction of the organ increase, and as the site of the perforation descends in the intestinal tract.
9. Paradoxical as it may seem, the mortality decreased in inverse proportion to the length of the operation.
10. Shock and hemorrhage accounted for the greatest number of deaths.

1913 Church Street.

ABSTRACT OF DISCUSSION

DR. ADOLPH A. WALKLING, Philadelphia: Whenever the abdominal wall has been penetrated by a bullet, exploration should be done. The patient may have signs of shock which may be due to fright, while the signs of perforation, such as pain, tenderness, rigidity and presence of air in the abdominal cavity, may be entirely lacking. When the patient is seen and his condition is satisfactory to withstand operation, no delay should be permitted. The most urgent problem is hemorrhage and it is difficult to differentiate hemorrhage and shock. At the Pennsylvania Hospital our mortality in the cases of severe hemorrhage was 61 per cent, in the moderate hemorrhage cases 39 per cent, and in the slight hemorrhage cases 26 per cent. The points made regarding multiple wounds and the fatal types of combined colon perforation with severe hemorrhage are well taken. That wounds in viscera may be overlooked and cause death was emphasized by Billings and myself in 1931. The more experience the operator has, the less are wounds overlooked. In the nine cases in which lesions were overlooked the condition was very critical at the time of operation and all were wounds of the upper abdomen. One can appreciate the difficulty of finding wounds of the kidney, pancreas and upper surface of the liver in a patient who has severe abdominal hemorrhage and whose condition is critical. Several of these had failed to show any reaction from shock after the use of the usual antishock measures, and their condition had rapidly changed from bad to worse because of continued bleeding, the operation having been done primarily for the control of hemorrhage. Under such circumstances the amount of the anesthetic and the time required for the operation assume more than the usual importance in the result. It is in such cases that blood transfusions will be of the greatest value. We have available in the blood bank at the Pennsylvania Hospital this morning 3,000 cc. of blood and 10,000 cc. of plasma. We prefer to give blood or plasma on the operating table. It is

our policy to explore the entire intestinal tract from the stomach to the rectum and to do it carefully and, if possible, inspect all organs and examine carefully for retroperitoneal hemorrhage. X-ray examination before operation in gunshot cases is a useless procedure. Our low mortality is due in a great measure to early operation and the liberal use of the blood bank for transfusions of plasma and blood.

DR. WALTER E. LEE, Philadelphia: The mortality from gunshot wounds of the abdomen in civil life has not been greatly reduced during the last twenty-five years. The unusual number of cases which Dr. Rippe reports does not make me envious, but I must confess surprise. His mortality of 61.9 per cent in gunshot wounds of the abdomen with visceral injury we match at the Graduate Hospital in Philadelphia with 53.2 per cent, slightly higher than Dr. Walkling's of 50 per cent, but it would seem that an average mortality of 50 per cent could be accepted in the United States at the present time. I agree with Dr. Rippe that the time interval between the receipt of the injury and the operation is the most important factor in influencing the end result. The better results which have apparently been obtained at the Pennsylvania and Graduate hospitals I feel are largely due to the emergency transportation service. Second in importance is the rapidity with which the operation is performed. The operating room is at all times prepared for such emergencies, and within thirty minutes after the request is made, night or day, the operating room will be ready to function. Next in importance is the availability and use of the blood bank for transfusions of whole blood and plasma, in the accident wards and the operating rooms. Last, but probably not least, in both of these hospitals for the last ten years residents in surgery, or fellows, have been in charge of the accident ward service, supplemented by staff assistants who make it possible at all times to operate within thirty minutes, if necessary. In my experience a patient who has not reached the operating room within two hours after the injury falls into the class of delayed operation. In our group there was only one patient who recovered when operated on four hours after the receipt of the wound. I agree with Dr. Rippe that, next to the time interval, hemorrhage is the most important factor in determining mortality.

DR. THOMAS M. JOYCE, Portland, Ore.: There are two important points which Dr. Rippe brought out, one of which has been brought out many times in the past, but no amount of repetition can overemphasize its relation to low mortality rates, and that is early blood transfusion. That the high mortality in gunshot wounds of the abdomen is directly proportionate to this factor has been understood for many years, but unfortunately, owing to the catastrophic suddenness of these cases and often to their economic status, it is impossible to procure blood when necessary. It is for this reason that the institution of blood banks in our larger hospitals and in many military medical units is to be highly praised. The other important point is the fact that mortality rates vary inversely to the length of time of the operation. I feel that this is merely another measure of the skill and care on the part of the surgeon. A hurried operation, a hurried, incomplete search and a hurried closure all leave opportunities for overlooking damage. The point is also brought out by Dr. Rippe's figures that there is a certain limit to which a patient can be subjected to a surgical procedure under anesthesia. It is after the second hour that the mortality again begins to rise. Dr. Rippe's paper brings out the importance of careful surgery, skillfully performed in the early stages, with proper attention to secondary factors of shock and hemorrhage.

DR. R. ARNOLD GRISWOLD, Louisville, Ky.: Penetrating wounds of the abdomen are one of the greatest problems in our large Southern city hospitals. Dr. Rippe's paper is an excellent summary of his experience in Nashville and there is nothing in it with which I disagree. When these patients come into the hospital they can be roughly divided into three groups: (1) the group with obvious penetration of the peritoneal cavity and perforation of or trauma to an intraperitoneal viscus, (2) the group with obviously no penetration and no intraperitoneal damage and (3) a group in which it is not at first evident whether or not there is visceral injury. In the

first group, most of the patients die of hemorrhage. That is not according to the experience of those who saw such patients in base hospitals during the war. Rapid, early operation is essential and, as Dr. Rippy says, the appearance of shock in these people is not primary shock, it is due to hemorrhage and there is no excuse for delaying operation in order to treat shock. Once the abdomen is opened, stopping the hemorrhage is the first consideration and closing the perforation is the second consideration. Perforation of large vessels must be dealt with rapidly. These are a few details of operation that I have seen neglected. One of the most frequent gun shot wounds is that of the kidney or kidney pedicle. This is best handled by reflecting the colon medially, just as one would free it for a resection, and doing anterior nephrectomy rather than turning the patient over. Another is a wound of the stomach on the posterior surface. One should not hesitate about splitting the anterior surface wide open instead of trying to get around to the back of the stomach. There is, however, a second group of cases in which there is penetration and perforation of a viscus that we do not operate on. Those are patients who have shot gun wounds with bird shot, and ice-pick wounds of the abdomen. Shot gun wounds at close range are such large wounds, tearing so many large vessels, with so much visceral damage, that repair of them is inadequate; it just doesn't work. In the patient who is shot by bird shot at far range, even though there is penetration of a hollow viscus, these wounds seal themselves much better than the surgeon can seal them by any operative measure. That also applies to wounds caused by the ice-pick, which is one of our most common Southern weapons. In cases which I feel do not immediately fall into one of these classes one has to wait to determine the exact status. Waiting too long in a penetrating wound of the abdomen is disastrous. Therefore within the last year in these borderline cases, which run from 10 to 20 per cent, I have used peritoneoscopy.

DR. LEO ELOESSER, San Francisco: Under optimal conditions in the best hospitals, with the best surgeons, the mortality of abdominal gun shot wounds is still appalling. The same holds true in military hospitals. I think that the reason is to be sought not in the promptitude with which the patients have come to operation but in the nature of the injury itself. Dumont of the Belgian Volunteers and Jolly of the Australian Volunteers in Spain, both with extensive experience in the treatment of abdominal war injuries, have stated that the fate of the abdominal injury is determined not so much by what is done as by the missile itself. In other words, if a man is wounded through the lower part of the abdomen, if besides a wound of the colon his large vessels are severed and he has a mesenteric tear with much hemorrhage, that man is going to die no matter whether one operates on him in a few minutes or in a few hours. If, on the other hand, a man is operated on who has, say, nothing but an injury to the liver, with some bleeding, he will probably live whether he is operated on early or late or whether he is not operated on at all. This has some bearing, I think, on the results of treatment not only in peacetime but much more so in wartime, because of the corollary that it is unwise to establish hospitals undertaking definitive treatment so close to the front as has been done in the past, with a view to treating abdominal injuries early. If the front line hospitals are established a little farther back we shall save many more patients by treating fractures efficiently than by attempting to treat abdominal injuries early. One other point: I think we may be a little too loath in these injuries to do enterostomies or colostomies or to extraperitonealize by packing off a conglomerate of intestinal coils badly damaged by a missile. If this was done more often, perhaps a few men might be saved who otherwise would be lost.

DR. ELKIN L. RIPPY, Nashville, Tenn.: In the Nashville General Hospital the mortality in the last three years has been lowered to around 51 per cent. This lowering of the mortality has been accomplished by the application of these principles: elimination of unnecessary handling, repeated transfusions, early exploration and the administration of sulfanilamide. Since preparedness is the keynote of America at the present time, let us as surgeons contribute our part by a thorough study of injuries as a result of gun shot fire.

HEAD INJURIES

H. C. VORIS, M.D.

ADRIEN VERBRUGGHEN, M.D.

AND

J. J. KEARNS, M.D.

CHICAGO

We are primarily concerned here with the management of patients with head injury admitted to the neurosurgical service at the Cook County Hospital. This service was formally established on Oct. 1, 1938. The present report is concerned with the patients admitted during 1939 (table 1).

In any statistical consideration of a series of patients the type of material and the criteria employed in the selection of cases are of importance. Our patients are admitted directly to the neurosurgical ward from the examining room of the hospital. They are persons who obviously have a head injury because of the external signs of trauma and patients who give a history of head injury followed by a period of unconsciousness.

A sizable group of patients have received a head injury but have no signs of cerebral damage. Another group are grossly intoxicated and, at the time they are seen in the examining room, it is impossible to tell whether or not they have a brain injury. These two groups are admitted for observation, and of course many of them later prove to have more or less serious cerebral

TABLE 1.—Results in 1,394 Cases of Head Injury Admitted to Cook County Hospital During 1939

Results	No. of Cases	Per Cent of Total
Recovered.....	1,111	79.7
Disabled.....	91	6.5
Dead.....	192	13.8
Within 6 hours after admission.....	45	3.3
Over 6 hours after admission.....	147	10.5

damage. Others do not and are dismissed after a brief period (from one to three days) of observation and x-ray examination of the skull.

In contrast to these we have a large group of elderly, ill nourished and debilitated patients in whom there is a high mortality from preexisting disease or from disease complicating their head injury. There were 479 patients (34.4 per cent of the total) in this series past the age of 50 (table 2). It will also be noted from table 2 that there were a large group of cases of unknown severely injured derelicts of whom we were unable to determine the age. There were 123 (8.8 per cent of the total) patients in this group with a mortality of more than 40 per cent. A large group of our patients are chronic alcoholic addicts. In this connection it is interesting to note that 545 patients (39.8 per cent) had the odor of alcohol on their breath at the time of admission.

These patients are all cared for in the services of the first two authors and are admitted in rotation to these services from the examining room of the hospital. We have pooled our statistics for the purpose of this report, and while there is no essential difference between the statistics for the two services it must be emphasized that

From the neurosurgical service of the Cook County Hospital and the Coroner's Laboratory of Cook County.

Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Orthopedic Surgery at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

the two services are conducted in the same ward and by the same nursing, intern and resident personnel but under the independent and individual supervision of the two authors mentioned. We have made no attempt to standardize our methods of treatment; we have made every attempt to make a statistical check against each other where there are differences in treatment.

Ideally, when a patient with a head injury first comes under observation an estimate should be made of the amount and extent of cerebral damage. Obviously, in many cases this cannot be done because of lack of adequate history, inability to carry out complete examination of the patient (because of shock and so on) and inability to correlate physical signs and symptoms with the organic brain injury present. From a practical standpoint some classification is essential and since 1934 we have used a purely clinical grouping. Our individual terminology has varied, but the grouping is the same: A, moribund patients, B, gravely injured persons, C, mildly injured persons and D, complicated cases. A fifth group of cases with late sequelae might be added, but obviously this is not of importance in the early management, except from the standpoint of prophylaxis. One of us (Verbrugghen) recently collaborated with

of a large "heat cradle," the source of heat being lighted electric bulbs. In cases of severe collapse, the patient is immediately placed in one of these without any attempts to remove his street clothing or to give him a bath. This is important, as well meaning nurses or attendants frequently add measurably to the patient's state of shock by unduly exposing him in their effort to remove his clothing, bathe him and otherwise "make him presentable." Obviously, if a patient is in shock the removal of his clothes and dirt, or even vermin, from his body should be postponed until his general condition has improved. One caution must be mentioned in connection with the use of external heat. Patients with brain injury, especially children, often have disturbance of the thermoregulatory mechanism. The rectal temperature should be taken hourly (every half hour in children), and as soon as it is over 100 F. the application of external heat should be discontinued. Other forms of heat, such as electric pads or hot water bottles, are equally efficacious. Some require greater caution to prevent burns of an unconscious patient.

Administration of fluid intravenously is often not only necessary but life saving to these patients. Obviously, large quantities of isotonic fluids should not be given to patients many of whom in a few hours will be liable to an increasing cerebral edema. Recent work (Coller and Maddock,² and White, Sweet and Hurwitt³) has shown the lack of necessity for administering sodium chloride unless there is abnormal loss of it, which is rare in these cases. Excessive chloride probably will promote development of edema in injured tissue. For this reason we prefer to administer dextrose dissolved in distilled water. A 10 per cent solution is mildly hypertonic and will at once increase fluid volume and reduce tissue edema. In our experience 1,000 cc. is an ample amount to give in most cases.

Stimulants are of value to the patient in marked collapse. Caffeine, nikethamide, strychnine or even powerful constrictors such as epinephrine or neosynephrin are used as indicated. Too rapid an elevation of blood pressure during the first few hours is to be guarded against, although doubtless its danger has been overemphasized.

Next to the immediate treatment of the shock or collapse, quiet is of the greatest importance in the management of a case of head injury. Manipulation of the patient is restricted to the minimum required for necessary examination and essential nursing care. X-ray examination is to be postponed until the patient is both out of danger and is conscious and cooperative. Attempts to obtain x-ray films earlier only endanger the life of the patient and usually end in failure because of lack of cooperation. The only exceptions to this rule are occasional special cases such as compound depressed fractures or suspected meningeal hemorrhage, and even here they are often better dispensed with. Until the patient has recovered from his initial collapse, surgical procedures including the suture of lacerations, reduction of other fractures or lumbar puncture must be postponed.

Sedatives are necessary in many cases and imperative in some. A wide choice is available. Morphine is always contraindicated at least in the early stages. We consider paraldehyde the most valuable single sedative

the late Dr. Fantus in an outline of the therapy of head injury¹ that discusses the treatment appropriate to each of these groups.

In this article the treatment of head injuries is discussed from the following standpoints: (1) symptomatic, (2) control of intracranial pressure, (3) treatment of complications, both surgical and nonsurgical, and (4) the prophylaxis and treatment of late sequelae.

SYMPTOMATIC

First and foremost is the treatment of the collapse (shock) which is so prominent in the cases of group A (moribund) and of considerable importance in group B (grave injury). These patients should have the head lowered, especially those who are stuporous or comatose and are vomiting or have considerable mucus in the upper respiratory passages. They should be on their side or face to prevent aspiration of mucus or vomitus into the lungs. After vomiting has ceased and the patient has regained consciousness or at least regained his pharyngeal and laryngeal reflexes, he may be left flat in bed. Most conscious patients (adults) seem to prefer being flat with perhaps one pillow, and we believe that the preference of the patient may well be followed in this respect.

External heat is of great value in the early care of these patients. It is applied in our service in the form

2. Coller, F. A., and Maddock, W. G.: Water and Electrolyte Balance, Surg., Gynec. & Obst. 70: 340-354 (Feb., No. 2A) 1940.
3. White, J. C.; Sweet, W. H., and Hurwitt, E. S.: Water Balance in Neurosurgical Patients, Ann. Surg. 107: 438-457 (March) 1938.

in the great majority of cases. There is a wide margin of safety in its use and it is rapidly excreted, so that it will not mask developing stupor or coma longer than a few hours. For the latter reason it has to be repeated every few hours if the restlessness or delirium persists. It may be given by mouth or rectum and repeated as necessary.

Mechanical restraints are necessary as a precaution for all patients not constantly attended or perfectly conscious, rational and cooperative. They are not to be considered as a substitute for sedation, as the patient who is allowed to thresh restlessly in his restraints is harming himself by this activity as much as any other. In many cases they are a poor substitute for the constant presence of a nurse or attendant, and often they infuriate an otherwise tractable patient. They are a necessity when constant attendance is impossible for economic reasons; otherwise many embarrassing or serious accidents will occur.

The nursing care of patients with head injury, particularly those in coma, is of great importance. The care of the skin is as important here as with any other bedridden patient and may be made difficult by coma, incontinence and debility. The bladder and bowel also require special attention. The latter usually receives it because of the importance of catharsis or enemas in reduction of cerebral edema. The bladder may be neglected. Voris and Landes⁴ have shown by cystometric studies that most patients with acute brain injury have bladders which empty reflexly with from 150 to 200 cc. of filling. However, in contrast to this, others have an atonic bladder with no contractions with from 500 to 600 cc. of filling. One of us (Kearns) has pointed out that relatively slight obstruction of the urethra, such as mild prostatic hypertrophy or urethral stricture in the male or cystocele or rectocele in the female, may prevent reflex emptying of the bladder of comatose or stuporous patients. Palpation or percussion of the bladder alone is not sufficient to determine whether or not there is retention; the catheter must be used. Cystometry, if available, will give exact information on the neuromuscular status of the bladder. Constant drainage with an indwelling catheter or the use of "tidal drainage" (Munro⁵) is necessary if there is any urinary retention; it is often advisable in cases of reflex emptying of the bladder to prevent the frequent soiling of the bed and consequent maceration of the patient's skin.

Drainage of cerebrospinal fluid from the nose or ears is positive clinical proof of a basal skull fracture. Drainage of blood is suggestive, especially if from the ears. In the case of either, no effort should be made to obstruct it. The only exception to this is the occasional profuse nasal hemorrhage which may require a pack to control. This should not be left in longer than a few hours. Any irrigation or mechanical cleansing of the ear or nose is to be avoided. In the case of drainage from the nose, the patient if conscious is to be cautioned against sneezing or blowing his nose. A pad of cotton or gauze may be taped loosely against the ear or nose to collect draining fluid and removed as often as necessary. The patient should be kept flat until the drainage stops.

CONTROL OF INTRACRANIAL PRESSURE

Cerebral injury is inevitably associated with at least local edema. It often is associated with marked increase in intracranial pressure. If edema or swelling of the brain is generalized, the cerebrospinal fluid is squeezed out of the subarachnoid spaces and ventricles and the brain presents the appearance of the so-called dry brain of the pathologist. Obviously, in these cases an accurate index of intracranial pressure is difficult to obtain by manometric measurement of ventricular or lumbar fluid pressure, especially the latter.

There are three methods available for the control of intracranial pressure following acute brain injury. The first of these is control of the fluid intake. The surgeon must order the amount and type of fluids that a patient is to receive, and the nurses and house staff must see that he does receive it. Obviously, it is necessary that nurses keep an accurate record of the patient's intake. A record of output is of great value but often difficult to obtain accurately. We ordinarily limit fluid intake to from 1,200 to 1,500 cc. in twenty-four hours. Conscious patients, of course, take this by mouth. Unconscious patients or stuporous patients must receive fluids by other routes. The intravenous method is usually employed. As previously stated, we do not give saline solution unless positively indicated but prefer 5 or 10 per cent dextrose solution in distilled water. Patients who are comatose more than three days should have nasal feedings of a high caloric and high vitamin liquid diet. Nasal feedings also provide for administration of drugs or cathartics.

Dehydration of a patient may be actively accomplished, when indicated, by saline cathartics, saline enemas or the intravenous administration of hypertonic solutions. The first two are so well known as hardly to need comment, but it might be remarked that the rectal administration by the drip method of from 200 to 400 cc. of a 50 per cent solution of magnesium sulfate will often be as efficient in the reduction of increased intracranial pressure as the administration of 100 cc. of 50 per cent sucrose intravenously and will be a great deal less drastic from the standpoint of effect on the circulatory system.

The intravenous administration of hypertonic fluids is of great value in many cases of brain injury and is disappointing in orders. Obviously this method requires an intact local circulation in order for it to work and of course the local circulation is more or less impaired at the site of cerebral contusion or laceration. From 500 to 1,000 cc. of 10 per cent dextrose or from 200 to 400 cc. of 25 per cent sucrose or from 50 to 100 cc. of 50 per cent sucrose are the concentrations and amounts most frequently used. Fifty per cent sucrose is very strongly hypertonic and is to be used with corresponding caution.

Drainage of cerebrospinal fluid by spinal or ventricular tap is a method of treatment concerning which there has been a great deal of dispute. Again it is a method of great value in certain cases, disappointing in others and at times positively dangerous. The danger would seem to be principally that of producing a herniation of the cerebellar tonsils into the foramen magnum or of the hippocampal gyrus into the incisura tentorii because of marked increase in intracranial pressure and relatively low cerebrospinal fluid volume. Ventricular drainage, which is of such great value in certain cases of intracranial tumor, has had little trial in cases of

4. Voris, H. C., and Landes, H. E.: Cystometric Studies in Cases of Neurologic Disease, *Arch. Neurol. & Psychiat.* 44: 118-139 (July) 1940.

5. Munro, Donald: Craniocerebral Injuries: Their Diagnosis and Treatment, New York, Oxford University Press, 1938. Munro, Donald, and Hahn, Joseph: Tidal Drainage of the Urinary Bladder, *New England J. Med.* 212: 229-239 (Feb. 7) 1935.

brain injury. It certainly deserves further trial. Cisternal puncture will always be contraindicated where lumbar puncture is in cases of head injury. If there is danger of herniation at the foramen magnum, cisternal puncture is dangerous if not impossible because of the obliteration of the posterior cistern by the prolapsed cerebellum.

TABLE 3.—Results of Treatment by Cerebrospinal Fluid Drainage and Hypertonic Fluids

Treatment	Living	Dead	Total	Mortality Rate
Cerebrospinal fluid drainage alone..	37	8	45	17.8
Hypertonic fluids alone	145	86	231	37.2
Cerebrospinal fluid drainage and hypertonic fluid	67	35	102	34.4

Our attitude toward these methods can be best shown by the fact that of 1,394 patients only 231 were treated with intravenous administration of hypertonic solutions, with a mortality for the group of 37.2 per cent. Forty-five were treated with lumbar drainages (receiving at least two) with a mortality of 17.8 per cent. Another group of 102 patients received both forms of treatment with a mortality of 34.4 per cent (table 3). The mortality rate in these groups is not a fair criterion of the efficacy of the two methods, for these were selected cases and spinal drainage was not used on many of the desperately injured patients who did receive intravenous hypertonic solutions.

TREATMENT OF COMPLICATIONS

The treatment of complicated cases naturally resolves itself into the treatment of surgical and nonsurgical complications. In our present series of cases only a relatively small group (2.3 per cent) have been treated surgically. Table 4 presents a synopsis of this group. The mortality was high (50 per cent) and the post-mortem observations indicate that this is due to two factors, associated cerebral injury and pulmonary complications, the two often occurring in the same patient. One of us⁶ has recently published the results of operation in a series of subdural hematomas. In that series, as in the present one, the mortality was very high in the acute subdural hematomas, owing to the associated brain injury.

The indications for operative treatment may be briefly listed as (a) compound depressed skull fracture, (b) certain simple depressed fractures and (c) extracerebral hematomas. Patients with compound depressed skull fractures are to be operated on with débridement and primary suture within the first eight to ten hours if the condition of the patient permits. Otherwise the wounds are to be left open or loosely approximated and allowed to heal by secondary intention. The fracture then may be elevated as an elective procedure if this is indicated. Unfortunately, if the wound becomes infected in the presence of comminuted fragments of bone an osteomyelitis will usually result, and often meningitis or brain abscess.

The elevation of a simple depressed fracture is almost always an elective procedure and should be delayed until the patient is out of danger. Rarely it may produce local neurologic symptoms or more rarely increased intracranial pressure and require early elevation. Many

depressed fractures cause no symptoms and may be left alone. It is our practice to elevate those in the frontal region for cosmetic reasons and those near the motor area because of the frequency of post-traumatic epilepsy associated with depressed fracture.

Extracerebral hematoma, especially extradural, is of course an indication for operative intervention. We have already called attention to the futility of operating on the acute subdural hematoma, although occasionally a patient is benefited. It appears that subdural bleeding sufficient to produce a hematoma large enough to cause pressure symptoms is almost invariably associated with severe brain contusion or laceration. Chronic subdural hematoma develops slowly with a gradual onset of symptoms. Associated brain injury is usually slight and the patient has ample time to recover from it before evidence of his hematoma appears. The operative results are correspondingly good.

The diagnosis of an extradural hematoma in a typical (so called) case should be easy. This is due to the fact that there is no severe associated brain injury and therefore the classic "lucid interval" is present. Then too there is an uncomplicated development of localizing signs. Unfortunately, the "typical" cases are in the minority as associated brain injury of considerable severity is often present. Thus patients are stuporous or comatose from the onset and localizing neurologic signs due to brain injury may be present from the onset. Then too the development of localizing signs may be masked in whole or part by preexisting coma. Careful watch must be kept on all comatose or stuporous patients for the deepening of coma and the appearance of new localizing signs or of signs of increasing intracranial pressure. Since acute brain injury can and does often simulate the picture of a progressive lesion, an exploratory burr hole under local anesthesia must often be resorted to. Six (18.8 per cent) of our thirty-two patients who were operated on had no extracerebral hematoma but they did have brain contusion or laceration. One patient had a subcortical hematoma which was not found at operation. In the seventy-four necropsies performed, extradural hematoma was considered the principal cause of death by one of us (Kearns) in eight cases (10.8 per cent). Two of these

patients had been operated on (table 5), leaving six (8.1 per cent) unrecognized cases. This illustrates the frequency and difficulty of recognition of the atypical case.

We do not consider decompression to be of therapeutic value per se in cases of brain injury. First of all, no matter how skilfully performed it can only add to the trauma and edema already present. Secondly, it has been our observation in performing routine decompressions in cases of inoperable brain tumors that it requires several days to a week before adjustment of the intra-

6. Voris, H. C.: Diagnosis and Treatment of Subdural Hematomas, Proc. Inst. Med. Chicago 13: 129-130, 1940.

cranial contents to the decompression takes place and signs of clinical relief as cessation of headache and vomiting and recession of papilledema appear. Obviously, a therapeutic procedure offering such tardy relief will be of little value in the treatment of acute brain injury.

The most important nonsurgical complications that we have to deal with are meningitis, toxic psychosis, pneumonia and cardiovascular and renal disease.

The incidence of meningitis in this group was low: seven cases (0.5 per cent) with four deaths. This is of interest in conjunction with the fact that there were forty-one cases in the series with drainage of cerebrospinal fluid to the exterior from either nose, ears or a compound depressed skull fracture. In this connection it might also be noted that there were 703 cases of scalp laceration in the series; only nineteen (2.7 per cent) became infected. A number of these had been sutured elsewhere before admission to the Cook County Hospital. The new methods of chemotherapy have in our hands, as in others, greatly reduced both the incidence and the mortality of intracranial infection. There were no cases of brain abscess in this series.

Many of our patients are chronic alcoholic addicts. We have already referred to the large number of patients who had the odor of alcohol on their breath at the time of admission. Further, many of these patients

hope of financial compensation as a result of their injury. We do have patients with persistent headache, dizziness, easy fatigue or personality change but they are relatively rare compared with the number seen in private practice. We do not believe we can assume that our treatment is entirely responsible for this. It is our practice to insist on a minimum of two weeks of

bed rest for all patients unconscious more than fifteen minutes, all patients who have bloody spinal fluid and all patients with roentgenographic or clinical evidence of fracture of the skull. In addition, patients with mild injury that complain of persistent headache or dizziness for more than three or four days after the injury are placed on a more strict regimen of fluid limitation with fluids limited to 1,000 cc. in twenty-four hours and daily saline catharsis. This seems to be of real value in preventing post-traumatic sequelae in this type of case. To be effective it must be carried out early after the injury. Cases seen later with the post-traumatic syndrome rarely respond to this management.

During 1939 there were 1,394 patients with head injury admitted to the neurosurgic service of the Cook County Hospital. Table 1 gives the results. The disabled group includes only those patients who left the hospital with a neurologic defect that was expected to be permanent. Table 2 shows the distribution of cases by decades with mortality rates. This table shows strikingly the importance of the age of the patient in determining his chances for recovery. Many other authors have commented on this.

Necropsies were performed by one of us (Kearns) in seventy-four cases, or 38.5 per cent of the deaths. Table 5 gives what was considered to be the principal cause of death in these cases. It has already been noted that in twenty-one cases (28.4 per cent) of the nec-

were debilitated and chronically malnourished. As a consequence, the incidence of toxic psychosis was high. This condition when associated with head injury is exacerbated by dehydration of the patient. It is essential to push fluids on these patients and to give ample sedation. At times some sedatives, especially the barbiturates, have a toxic effect and may add to the confusion and delirium. When the vital centers (cardiovascular and respiratory) seem intact we may make an exception to our usual rule and use morphine as a sedative. It is also our impression that spinal drainages, especially when the fluid intake is kept high, are of value in treating these cases. Needless to say, they are performed only with the patients under ample sedation.

The incidence of pneumonia and cardiovascular, renal and other associated disease was high. Of seventy-four necropsies one of us (Kearns) considered the principal cause of death to be unrelated to the head injury in twenty-one cases, or 28.4 per cent (table 5).

PROPHYLAXIS AND TREATMENT OF SEQUELAE

Sequelae of course cannot be adequately considered in our present series. We hope at a later date to present from the records of our follow-up clinic a complete study of the late effects of the head injury in this group of patients. We would, however, call attention to the fact that ninety-one patients (6.5 per cent) suffered some degree of permanent loss of neurologic function. Another point worth emphasizing is the relative rarity of cases seen in the follow-up clinic with subjective post-traumatic symptoms. Most of our patients have no

ropsies the principal cause of death was miscellaneous associated injury or disease. In a large group of cases (25.7 per cent) there were subdural hematomas. These were practically all of the so-called acute type. We have already called attention to the high operative mortality in acute subdural hematomas and to our belief that only the occasional case of this group should be treated surgically.

The mode of injury is of considerable interest in dealing with cases of head injury. Table 6 shows that our patients can be divided into four almost equal

groups, one injured by automobile accidents, another by some form of assault, another by falls and a fourth by miscellaneous or unknown causes. The high percentage injured by falls speaks for a high percentage of alcoholism and syncopal attacks; the high percentage injured by unknown causes includes a large group of critically injured persons who were picked up by the police and brought in without any history.

Seven hundred and ninety patients suffered associated injuries to other parts of the body, often multiple and most frequently the face, extremities and chest. Table 7 gives the detailed figures for the location of these injuries.

COMMENT

1. In this group of patients, age seemed a very important factor in determining survival.

2. Associated injury and disease are important factors in determining survival. This is especially true in the older age groups.

3. There was a comparatively low percentage of cases in which surgical operation was performed. In this group of cases acute subdural hematoma proved to have a high surgical mortality, and we believe that operation should be done only in the rare case of this group. Chronic subdural hematoma is a much more favorable lesion from the surgical standpoint and operation is always indicated in these cases.

4. Watchful conservatism gives the best results in the management of head injuries. Supportive treatment, enforcement of rest and careful nursing care and observation pay high dividends.

5. Special methods of reduction of intracranial pressure are of value in selected cases. Their routine use is to be condemned.

6. Approximately 40 per cent of patients dying of head injury have no demonstrable skull fracture at necropsy. This shows the absurdity of relying on the presence or absence of fracture of the skull in determining prognosis or treatment.

ABSTRACT OF DISCUSSION

DR. S. BERNARD WORTIS, New York: Drs. Voris, Verbruggen and Kearns have emphasized the problems of the complications and management of head injury. Our material of 1,000 cases at Bellevue Hospital (Wortis, S. B., and Kennedy, Foster: *Surg., Gynec. & Obst.* 55:365 [Sept.] 1932) is in agreement with their observations. One can only emphasize again the points which they brought out: 1. The mortality rate varies with age. In our group we found that children under 12 had a mortality rate about one-half that of adults over 60. 2. We found that in this city automobile accidents and falls were the commonest causes of head injury. 3. Roentgenograms gave positive evidence of skull fracture in only about half of the patients, so that one cannot depend alone on the skull x-ray examination for determining the degree of severity of any head injury. 4. Autopsies were performed on 380 of our patients, and of these we found skull fractures present in 97 per cent; we found gross brain laceration present in 92 per cent of our autopsy material, and a very low incidence of sepsis; suppurative meningitis in only fourteen cases, and brain abscess in only two cases. 5. Seventy per cent of the people with head injuries admitted to Bellevue Hospital had bleeding from the cranial orifices. 6. Eighty-five per cent of the patients showed clinical evidence of neurologic disturbance of brain function. Ten per cent showed papilledema, 10 per cent had peripheral facial palsy, and generalized convulsions were found in about 110 of the 1,000 patients. We performed skull operations on thirty-seven patients, and in this group the mortality rate was about 50 per cent, so that our

treatment has become, as the years go on, more and more conservative. One can only emphasize the fact that the more conservatively one treats these head injuries the more effective the results will be. I agree entirely with the authors' suggestion that no one method of treatment seems to be effective; one must vary one's treatment depending on the clinical observations. Some patients require hypertonic solutions for the reduction of intracranial pressure; other cases do not. Any simple single formula meant to apply to the treatment of all cases of head injury is a detrimental formula.

DR. DONALD MUNRO, Boston: This subject is important because, as one's experience increases with head injuries, it becomes apparent that some day it is going to be the duty of the general surgeon to care for the majority of them, leaving only the difficult ones to the specialists. This paper emphasizes the number of head injuries that occur and covers the first two years following the establishment of the authors' service. My experience has also been in a municipal hospital, but it covers ten years, so perhaps I may be allowed to comment adversely on some of the more important points. I should like to comment on the 38 per cent of autopsies that the authors have had. I have been so fortunate as to have had four out of five, or slightly more, of my head injury autopsies done for me by the medical examiner of Suffolk County. From those autopsies I have learned more about how to handle and diagnose these cases than from any other single factor. In their summary the authors do not classify compound fractures separately. My experience has been that there are a considerable number of compound fractures in any group of head injuries and that their presence materially influences the ultimate mortality and that therefore their segregation is imperative. I am interested in the small number of extradural and subdural hematomas that they have had. I have had about 2,000 cases in the ten years as compared with their 1,300 in one year. In those 2,000 cases I had over forty-four extradural hematomas, as proved by either operation or autopsy. In that same group I had about 300 subdural hematomas. I do not think that there is any reason to differentiate between the acute and the chronic subdural hematomas. After all, every chronic hematoma is acute at its start. Since the chronic stage necessarily carries a lower mortality such a division gives false figures relative to the efficacy of any therapy, I feel strongly that subdural hematomas should be operated on early, and I always feel bad when the medical examiner finds in one of my cases a subdural hematoma that I have not had a chance to treat. In the first 225 of the 300 subdural hematomas that I experienced my operative mortality was 34 per cent. The most important point of difference between myself and the authors has to do with diagnosis. I don't believe that we shall ever get anywhere in learning about this subject until we base our classification of these cases on some universally recognized diagnosis.

DR. JOHN P. STUMP, New York: This paper makes the point that the report of the authors is based on cases of injury not only to the cranium and its contents but also to the rest of the body. Injuries to parts other than the head are important. Many reports have come from services that got their patients late or received patients with head injuries only. At Gouverneur Hospital in New York the patients with head injuries are admitted to the fracture and orthopedic service. They are seen almost simultaneously by a member of the fracture and orthopedic staff and a neurosurgeon. The neurosurgeons are not regarded as consultants, nor are we; we both participate in the treatment of these patients. We have recently reviewed the cause of death of patients having proved cranial or intracranial injuries, and of these approximately 20 per cent died of their head injuries alone, while 30 per cent of the patients who died had mortal body injuries and very slight intracranial injuries. The point I make is the importance of considering injury to the rest of the body, as well as to the head, as a potential cause of death.

DR. HAROLD C. VORIS, Chicago: I too wish we had more necropsies. We are thankful for the ones that we do have, which we owe to the cooperation of Dr. Kearns, the coroner's physician. The absence of skull fracture in from 35 to 40 per cent

of patients dying from head injury is based not only on this series but also on a much larger series collected by Dr. Kearns during previous years in the coroner's laboratory. It is therefore surprising that Dr. Wortis could demonstrate skull fractures in 97 per cent of necropsies in his series. In classification of cases, one can of course by proper selection make a mortality rate as high or as low within certain limits as wished. Therefore, in this preliminary paper we have reported our first year's experience, not with any particular type of head injury, but with the management of all cases of head injury admitted to a large neurosurgical service. I must defend the clinical classification of cases at the time of admission. I agree with Dr. Munro that in the end we must attempt to classify the patient according to the brain injury which we could or thought we could demonstrate. We have already pointed out that to begin with that is often not possible. If one attempts it one often has to change one's opinion within a short time. So from the standpoint of treatment and of early management the clinical grouping mentioned is most satisfactory. I wish we could report the results in acute subdural hematoma that Dr. Munro has. Frankly, our experience with acute subdural hematoma has not been sufficiently good to warrant our continuing to operate on these patients. I agree that there is no need to differentiate the cases preoperatively from extradural hematomas, and, whenever the latter is suspected, exploration should be made. On the other hand, although acute subdural hematomas represent the first stage of a possible chronic subdural hematoma, it is important to differentiate them clinically. The acute subdural hematoma is a large collection of blood without neomembranes, practically always associated with acute brain injury and with a high mortality. The chronic subdural hematoma was originally small and has neomembranes, the patient has recovered from his brain injury and the mortality is correspondingly low.

NEUROGENIC FACTORS IN THE PRODUCTION OF ACUTE GASTRIC ULCER

RUSSELL S. BOLES, M.D.
AND
HELENA E. RIGGS, M.D.
PHILADELPHIA

Study of fifteen cases of acute gastric ulceration associated with primary intracerebral disease shows no essential pathologic difference between these lesions and the acute gastric ulcer found in the absence of such disease. That the mucosal lesion is the result of an acute phase of gastric circulatory deficiency of a prolonged type is suggested by the presence of chronic degenerative changes in the deeper layers of the stomach wall. Moreover, similar degenerative changes dependent on chronic stasis in the circulatory beds found in other viscera in these cases demonstrate that the so-called "neurogenic" ulcer is not a primary, isolated phenomenon but a focal manifestation of subclinical generalized circulatory insufficiency.

The absence of organic cardiovascular disease in this series, with a mean age of 34 years, permits the assumption that the generalized peripheral circulatory disturbances noted in the viscera mentioned are primarily related to an intracerebral condition. The nature of the pathologic alterations in the viscera suggests that the stasis in the peripheral circulation develops from prolonged vasoconstriction due to stimulation of the cerebral vegetative centers by the primary intracranial

disease. Assumption of a relationship between the peripheral circulatory abnormalities, the gastric lesion and central vegetative stimulation is based not only on the demonstrated pathologic alterations in the viscera

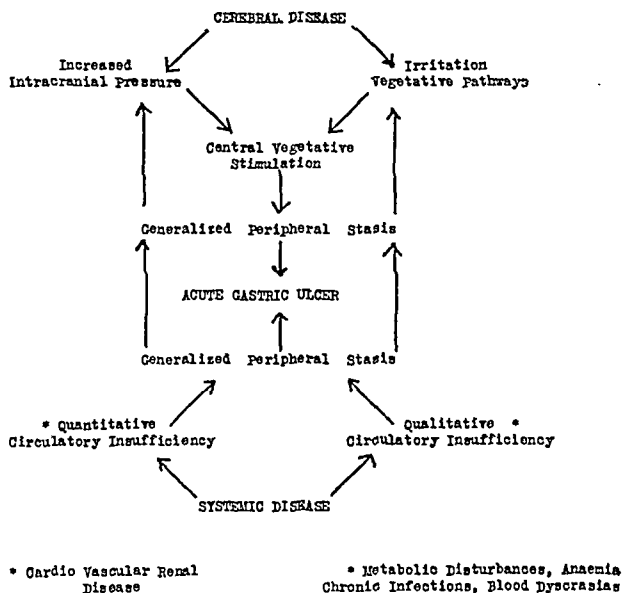

Fig. 1.—Mechanism of acute gastric ulcer.

mentioned but on the location and nature of the cerebral lesion (table 1).

In the cases we are presenting, stimulation of the central vegetative nuclei resulted either from increased intracranial pressure from tumor or abscess within the cranial cavity, or from irritation due to a focal lesion of the central vegetative pathways.

Destruction of the central vegetative nuclei was not an etiologic factor in these "neurogenic" ulcers. In ten cases of expanding new growths associated with acute ulcer it is believed that the ulcer was the direct result of stimulation of the hypothalamic centers from increased intracranial pressure rather than destruction of the centers by the cerebral lesion itself. This is well illustrated by the four cases of tumor involving the

hypothalamic centers. Here the centers were affected by compression of the blood supply rather than by actual invasion of the tissue. On the other hand, the five cases not associated with increased intracranial

pressure, while involving the vegetative areas, were essentially characterized by lesions which would result in irritation rather than destruction.

Thus, in this series of "neurogenic" ulcers it is possible to demonstrate a central etiologic factor, namely

Fig. 3.—Systemic circulatory disturbances in primary intracerebral disease: Section of heart of a person, aged 29, with primary brain tumor. Venous channels are greatly dilated. Trichrome stain.¹ Reduced from a photomicrograph with a magnification of 71 diameters.

blood supply; however, excessive stimulation of this physiologic mechanism may result in anoxia of tissues and later in increased capillary permeability, tissue edema and decreased circulating blood volume. Tissue edema, thus established, augments the irritability of the cerebral centers through the mechanism of asphyxia and, because of its demyelinating effects on peripheral nerve pathways, may render the entire vegetative system sensitive to subminimal stimuli. In turn, the vasoconstriction of vessels resulting from abnormal neural irritability aggravates the preexisting stasis.

Fig. 5.—Systemic circulatory disturbances in primary intracerebral disease: Section of kidney of a person, aged 29, with primary brain tumor. There is marked increase of perivascular connective tissue. There is thickening of Bowman's capsule and hyalinization of the glomerular capillary tufts. Trichrome stain.¹ Reduced from a photomicrograph with a magnification of 92 diameters.

stimulation of the central vegetative mechanism, which in turn causes the stasis or vasoconstriction responsible for the ulcer. While emphasis has been placed on the role of changes in the peripheral circulation due to stimulation of the sympathetic system in the production of ulcer, we appreciate that parasympathetic stimulation must be considered because of similar demonstrable pathologic alterations in this system.

While the intracranial lesion is the immediate factor initiating cerebral vegetative activity, the stimulating

effects of the resulting peripheral circulatory disturbances on the vegetative system itself may establish a vicious cycle. Normally, peripheral vasoconstriction due to central vegetative control insures adequate cerebral

On this premise the basic mechanisms underlying acute gastric ulcer associated with intracranial disease, and ulcer unassociated with such disease, differ only in the nature of the primary factor responsible for the circulatory insufficiency. In "neurogenic" ulcer the pressor effect of central vegetative stimulation by the intracranial lesion initiates the peripheral stasis; in other forms of acute focal gastric lesion the same end result is produced by quantitative or qualitative alterations in the general circulation.

Although it is possible to distinguish neurogenic and visceral factors initiating the peripheral circulatory imbalance which we believe underlies acute gastric ulceration, the blood stasis resulting from such imbalance by its effect on the nervous system establishes a secondary neural cause for all such lesions regardless of

No cerebral complications.....	34	20

the primary etiologic factor. In some cases in which the gastric lesion is not associated with intracranial disease, the influence of this neural factor alone may be sufficient to produce acute gastric ulceration. Generally speaking, however, central vegetative stimulation

cerebral disease (table 2); in ulcers unassociated with intracerebral disease, these same stimulating factors are established by deficiencies in the cerebral circulation resulting from the generalized circulatory insufficiency accompanying systemic disease.

Fig. 7.—Alterations in peripheral vegetative system in primary intracerebral disease: Section of vagus nerve (intrathoracic portion) of a person, aged 27, with primary brain tumor. Nerve fibers separated by edema. Patchy demyelination with generalized increase in interstitial elements. The remaining myelin sheaths are swollen and vacuolated. Weil myelin sheath stain. Reduced from a photomicrograph with a magnification of 149 diameters.

The influence of central vegetative stimulation in bringing about circulatory insufficiency in systemic disease, thereby precipitating acute gastric ulcer, is demonstrated in table 3. In systemic disease, 82 per cent of the cases with ulcer presented evidence of increased intracranial pressure or changes in the central vegetative pathways which were secondary to the cerebral effects of peripheral circulatory insufficiency. Furthermore, ulceration occurred four times more frequently in cases of primary systemic disease with secondary central vegetative stimulation than in those without such stimulation of the central nervous system.

CONCLUSIONS

- 1. "Neurogenic" ulcer is a focal expression of sub-clinical generalized circulatory insufficiency, initiated through stimulation of the central vegetative mechanism by primary intracerebral disease.
- 2. In the absence of primary intracerebral disease, changes in the vegetative nervous system resulting from circulatory insufficiency may exert a neurogenic influence in ulcer production.

Fig. 6.—Alterations in peripheral vegetative system in primary intracerebral disease. Section of lumbar sympathetic ganglion (vertebral chain) of a person, aged 27, with primary brain tumor. Intense stasis. Loss of ganglion cells. Remaining cells show ischemic degeneration. Marked increase in interstitial tissue. Trichrome stain.¹ Reduced from a photomicrograph with a magnification of 69 diameters.

appears to be the predominant factor in the production of acute gastric ulceration whether it is of the non-neurogenic or the neurogenic type. In "neurogenic" ulcer the factors responsible for such central stimulation (namely increased intracranial pressure or lesions of the vegetative pathways) are due to the primary intra-

Functional Murmurs.—Potain made the most exhaustive study of functional murmurs. He found such murmurs present in one eighth of all the patients seen in his hospital service. They were present in practically all of the cases of Graves' disease, in 50 per cent of the cases of chlorosis, 25 per cent in measles and scarlet fever, 10 per cent in pulmonary disease. . . . The student should not gain the impression that functional murmurs are truly "accidental" and to be altogether disregarded. Often they may, quite often they may not, be disregarded. A relative insufficiency of the mitral valve due to an enlarged left ventricle produces a systolic murmur which is functional so far as there is no organic pathological process on the mitral leaflets. Such a murmur, however, may be of as great as or greater importance than the systolic organic murmur of an almost perfectly functioning mitral valve.—Major, Ralph H.: Physical Diagnosis, Philadelphia, W. B. Saunders Company, 1940.

FATAL HEMORRHAGE FROM
PEPTIC ULCERONE HUNDRED AND SIXTEEN CASES COLLECTED
FROM VITAL STATISTICS OF SEATTLE DURING
THE YEARS 1935-1939 INCLUSIVE

JOHN M. BLACKFORD, M.D.

AND

ROBERT H. WILLIAMS, M.D.

SEATTLE

The mortality risk of hemorrhage from peptic ulcer has been reported by various observers¹ as varying from a fraction of 1 per cent to as high as 74 per cent, the last figure reported by Chiesman² in a selected group of recurring hemorrhages. Allen³ and Blackford and Cole⁴ reported simultaneously (1937) that in older persons having massive exsanguinating hemorrhage the mortality rate approximated 30 per cent in their hospital practice and that age was the greatest factor influencing mortality.

Recent reports of mortality rates of from 1 to 2 per cent for hemorrhage from peptic ulcer when under special medical treatments have been made by Meulengracht,⁵ Andreson⁶ and others; and Hurst⁷ feels that a death in private practice from hemorrhage from ulcer is rare. On the other hand, Hinton,⁸ Goldman,⁹ Crohn¹⁰ and many others report higher mortality rates, often much higher.

The wide variation in mortality statistics must be due to a difference in the type of cases included for study by the various authors. Most reports include all cases admitted to the hospital for gross hemorrhage, regardless of age or the seriousness of the hemorrhage. Some medical men have excluded surgical deaths from their statistics. Many reports include patients bleeding from marginal ulceration. No report includes the mortality outside of hospitals.

Last year Blackford and Cole⁴ reported all deaths during two years considered due to hemorrhage from peptic ulcer, as recorded by the Seattle Bureau of Vital Statistics, together with their clinical experiences with hemorrhage from peptic ulcer. Gross hemorrhage from ulcer was defined as that evidenced by hematemesis or melena without regard to clinical symptoms, and massive hemorrhage as gross hemorrhage with great loss of blood plus critical symptoms of acute anemia. It was noted that early blood determination gave little or no information that was of value. Only 40 per cent of all first hemorrhages in the series occurred in patients past 45 years of age. Half of the hemorrhages in older patients were massive hemorrhages.

VITAL STATISTICS

We now present all deaths recorded with the Seattle Bureau of Vital Statistics during the five years 1935-1939 inclusive in which it seems reasonably certain that the patient died as the result of hemorrhage from peptic ulcer. Death due to hemorrhage from peptic ulcer is so startling an event that the physician should not fail to note the hemorrhage on the death certificate; for this reason, the list should be fairly complete.

These cases have been collected as follows: All death certificates (23,955) were reviewed individually, and each certificate on which the fatality was attributed to hemorrhage from peptic ulcer was listed for study. The cross index of vital statistics was not relied on because of the chance of clerical error; and some errors were found for the two years previously reported.⁴ All cases were traced back to hospital records, to the physician who signed the certificate or to the family of the deceased. One coroner's case could not be traced.

The list includes all cases in which death was apparently properly attributed to hemorrhage from peptic ulcer. The tracing back to clinical records allowed the elimination of a few cases which we felt should not be included, particularly (1) bleeding from gastroduodenal or marginal ulceration, (2) sudden fatal gastric hemor-

Chart 1.—Distribution of 116 deaths from peptic ulcer hemorrhage among 23,964 deaths.

rhage which was the only evidence of ulcer, (3) acute hemorrhagic gastritis and (4) gastric hemorrhage which was manifestly not the immediate cause of death.

The records of ninety-seven men and nineteen women, or 116 cases in all, have been thus collected as representing all deaths in Seattle during five years which were considered due to hemorrhage from peptic ulcer. Exactly half of these, fifty-eight, were confirmed by autopsy as death due to hemorrhage from ulcer. The high percentage of autopsies is due to the fact that most deaths reported were in hospitals with active post-mortem services and with competent pathologists in charge.

Autopsy records of these fifty-eight cases show that the hemorrhage was from gastric ulcer in thirty-seven and duodenal ulcer in seventeen, and that the location of the ulcer was not stated in four. Arteriosclerosis was recorded repeatedly on the death certificate as a contributing cause of death, as determined by autopsy.

Deaths attributed to hemorrhage from peptic ulcer but not studied by autopsy are, of course, not proved to be deaths due to hemorrhage from peptic ulcer. These cases were, however, so certified by the physician in charge. It is usually considered that approximately 90 per cent of gross gastric hemorrhages are hemorrhages from peptic ulcer. If we assume that only

80 per cent of clinical diagnoses not studied by autopsy are correct and that all the diagnoses confirmed by autopsy are correct, then the diagnosis of death due to hemorrhage from peptic ulcer should be correct in more than 90 per cent of these 116 cases.

Chart 1 shows by decades the total number of deaths in Seattle during five years and a superimposed curve shows the total number of deaths from hemorrhage from peptic ulcer during these years. It is evident that the great majority of deaths occurred between the ages of 50 and 70 years. Only three individuals were under 45. Their ages were recorded as 39, 42 and 43.

Chart 2 shows where these patients died: 22 per cent of them (twenty-six cases with eleven autopsies) at home—a group of fatalities never included previously in any clinical statistics on this subject; fifteen of the twenty-six patients dying at home were past 70 years of age. Sixty per cent of hospital mortality occurred in private general hospitals; and the private general hospitals in Seattle carry 66 per cent of the general hospital occupancy.¹¹

Almost all fatalities (97+ per cent) occurred in patients past 45 years of age, and less than 3 per cent were of persons under 45 years.

Most dramatic is the fact that 78 per cent of all fatalities (ninety cases) occurred following the first hemorrhage; only 22 per cent of all patients dying of hemorrhage from peptic ulcer (twenty-six cases) gave a history of previous hemorrhage.

Twelve patients who died had been operated on for emergency control of bleeding. One was operated on within forty-eight hours of the onset of hemorrhage and died of peritonitis on the tenth day; eleven were operated on from three to eleven days after the onset of massive hemorrhage.

Emergency operation on older patients in the first forty-eight hours of critical bleeding has rarely been undertaken in this country. We have found no report of a series of such cases. Later operation (after forty-eight hours) in critical cases has been followed by very high mortality rates.

Emergency operations in Seattle for hemorrhage from peptic ulcer are unusual. This is evidenced by the fact that not more than one surgical fatality has occurred during five years in any private hospital in Seattle and that two of the private hospitals have had no post-operative deaths. At the King County Hospital, six fatalities have followed the work of six different operators. No Seattle surgeon has had more than one death. Yet the city of Seattle has averaged two deaths each month from hemorrhage from peptic ulcer, and two thirds of those patients who died were under 70 years of age and were admitted to hospitals.

CLINICAL IMPRESSIONS

The clinical study of last year emphasized that, although 60 per cent of first hemorrhages from peptic ulcer occur in patients under 45 years of age, fatalities from hemorrhage are almost unknown in patients aged less than 45 years. The present study of the total mortality experience with hemorrhage from peptic ulcer taken from the vital statistics of a city of nearly 400,000 people shows how true that statement is.

The risk to life of hemorrhage from ulcer in younger patients is manifestly a small fraction of 1 per cent and the risk does not exceed 1 per cent even if only massive exsanguinating hemorrhages are considered. Therefore

one is rarely, if ever, justified in attempting to select those younger patients who are likely to die from hemorrhage from ulcer in order to consider operation as necessary to save their lives. No surgical procedure under such circumstances carries a risk of less than 1 per cent.

We have also pointed out that critical massive hemorrhage in older patients carries a mortality rate approximating 30 per cent, confirming Allen's report.¹² We also noted that five of our six fatalities followed the first hemorrhage. Allen³ reported 60 per cent of fatalities as following the first hemorrhage. It is usually taught that risk to life increases with each succeeding massive hemorrhage; yet three fourths of all fatalities reported in Seattle followed the first hemorrhage. It therefore seems certain that the first massive hemorrhage in older people is by far the most dangerous hemorrhage, a fact quite at variance with clinical impressions.

Surgeons have often remarked that risk to life increases with each recurring hemorrhage from ulcer; they have overlooked the fact that the mortality of all subsequent hemorrhages represents only about one fourth of the total mortality from bleeding ulcer. Three fourths of all deaths occur following the first hemor-

Chart 2.—Deaths from peptic ulcer hemorrhage.

rhage; only one fourth of all patients dying from ulcer hemorrhage have lived through a first hemorrhage to die later from another hemorrhage.

Such is the challenge of vital statistics for a reduction in the mortality of older patients. Bleeding from the ruptured, spurting, arteriosclerotic artery is apparently uncontrollable in one third of the cases of massive hemorrhage from ulcer in older people, unless it can be controlled by surgical intervention.

Occasionally, death from exsanguination occurs so quickly that there is no chance for any kind of intervention. Some patients are seen so late that operation is a last resort, and usually a forlorn hope, for life saving. Some patients are so handicapped by age or other infirmities that any surgical procedure is hardly to be considered. Still, the majority of these 116 patients whose bleeding resulted fatally were admitted promptly to hospitals and died from exsanguination a number of days later.

SURGICAL INDICATIONS

Finsterer,¹³ Gordon-Taylor,¹⁴ Hinton,⁸ Pfeiffer¹⁵ and many others believe that prompt operative intervention

12. Allen, A. W., and Benedict, E. B.: *Ann. Surg.* 98: 736-749 (Oct.) 1933.

13. Finsterer, H.: *Surg., Gynec. & Obst.* 69: 291-298 (Sept.) 1939.

14. Gordon-Taylor, Gordon: *Lancet* 2: 811-815 (Oct. 12) 1935.

15. Pfeiffer, D. B.: *Gastric Hemorrhage*, *J. A. M. A.* 111: 2198-2201 (Dec. 10) 1938.

should save many lives. Their reports give reason to hope that the record for critical hemorrhage in older people may be greatly improved by operation within the first forty-eight hours. After that time there is abundant evidence of terrific mortality following surgical intervention. It seems that tissue changes and bone marrow exhaustion after forty-eight hours of exsanguination make recovery from the shock of operation an unusual event.

Published reports of operative cases to date are, however, inconclusive in that patients operated on have not been grouped according to age. Many such operations have been done on younger patients. From the evidence of our clinical records, together with the evidence of vital statistics, the mortality risk of critical hemorrhage in younger patients is less than 1 per cent; hence operative intervention in such cases should actually increase the risk to life. In fact, we know of no surgical experience that justifies emergency operation for hemorrhage from ulcer in younger patients, even with prostrating hemorrhage. Less than 1 per cent will die if not operated on.

Forty-five years seems to be the age past which the risk of death from hemorrhage increases rapidly. In fact, nearly all fatalities are included in the group of older patients having critical hemorrhages from ulcer, and three fourths die following the first hemorrhage. The mortality rate would be well above 30 per cent in this group if all the massive hemorrhages shown in vital statistics could be included.

Operations done after unsuccessful attempts at supportive treatment through days of bleeding have usually resulted fatally. Eleven of the twelve patients cited as operated on in our vital statistics were operated on from three to eleven days after the onset of massive hemorrhage. Delayed operation at the Massachusetts General Hospital resulted fatally in 100 per cent of the cases.¹² All experience seems to show that operations done after several days of massive bleeding are followed by terrific mortality.

Prompt surgical intervention for critical bleeding from ulcer in older patients seems to offer the only hope of reducing the present mortality rate, which is above 30 per cent. An actual reduction in present surgical mortality should be accomplished by excluding younger patients from operation even when they are suffering critical hemorrhage from ulcer.

SUMMARY

All consecutive fatalities from hemorrhage from peptic ulcer during five years in Seattle show that:

1. Ninety-seven + per cent occurred in patients past 45 years of age.
2. Seventy-eight per cent died following the first hemorrhage.
3. Twenty-two per cent died at home.
4. Sixteen per cent were women.
5. Only twelve patients who died were operated on, each by a different surgeon.
6. Eleven of the twelve were operated on more than forty-eight hours after the beginning of hemorrhage.
7. Autopsy studies show more deaths from hemorrhage from gastric ulcer than from duodenal ulcer.

CONCLUSIONS

The vital statistics of Seattle show a remarkable number of deaths from massive hemorrhage from peptic ulcer in patients past 45 years of age, as contrasted with the very few deaths in those under 45. Three

fourths of all deaths resulted from the first hemorrhage. Prompt surgical control of massive hemorrhage seems to be the only hope of saving the lives of one third of the older patients having massive hemorrhage from peptic ulcer. This study gives further confirmation of the great risk of operations done after forty-eight hours of massive bleeding from ulcer.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. BOLES AND RIGGS AND
DRs. BLACKFORD AND WILLIAMS

DR. WALTER L. PALMER, Chicago: Drs. Boles and Riggs have shown pathologic alterations in the viscera other than the stomach in fifteen cases of acute gastric ulceration associated with primary intracerebral disease. These lesions may be due to circulatory disturbances. It would be interesting to know whether similar changes were found in patients dying of causes other than intracerebral disease and whether the changes were found both with and without gastric ulceration. The possibility that the lesions may be the result of the complex processes of death, of so-called agonal changes, does not seem to me to be excluded by the histologic evidence offered; in fact, acute gastrointestinal ulceration is seen not infrequently both in man and in the experimental animal in death from various causes. Perhaps such ulcerations are due to peripheral circulatory changes occurring in the last hours of life and perhaps the central nervous system does play a role in these circulatory changes. These assumptions, however, seem to be by no means proved; however, even if they are true they do not seem to warrant the further assumption that "the central vegetative mechanism has an important part either as a primary factor or a neurogenic complication in the etiology of acute gastric ulcer." Would it not be more appropriate to reverse the reasoning and to look on the ulcer as an incidental result or a localized manifestation of the complex processes leading to the death of the organism, which in these cases happened to be initiated by intracerebral disease? Drs. Blackford and Williams have approached the subject of massive hemorrhage from a new point of view and obtained results which emphasize still further the importance of this complication of peptic ulcer. I am impressed particularly with the seriousness of the first hemorrhage. Dr. Kirsner and I last year reviewed our cases of massive hemorrhage and found that five of eight deaths occurred in the first hemorrhage. We found that 1.8 per cent of our patients, numbering 165, under 50 years of age died, whereas the mortality rate of patients over 50 years of age was 7.6 per cent. It may be that surgery is indicated in this age group; however, at present, and under the circumstances obtaining in massive hemorrhage, I doubt that the surgical mortality rate will be found to be less than the 7.6 per cent obtained in our series with medical treatment.

DR. SIDNEY LEIBOWITZ, New York: These remarks are based on studies of Dr. Chasnoff and myself and express our combined opinions. We wish to compliment Drs. Blackford and Williams on their unique approach to the problem and their careful analysis of such material. The value of this study is enhanced by the fact that so large a percentage of the cases at autopsy proved to be instances of hemorrhage from ulcer. Our experience is based on studies of clinical material rather than fatalities alone. It has repeatedly been stressed that a large proportion of the fatal cases of ulcer hemorrhage occur in the arteriosclerotic age group. Yet to hear this figure placed at 97 per cent is unusual. In our own small series of ninety-three patients nine deaths occurred, of which five (55 per cent) were of patients older than 45. Equally surprising is the report that 78 per cent of the fatalities occurred after the initial hemorrhage. This finding is contrary to the prevailing impression and will undoubtedly alter our concept of the gravity of initial hemorrhage. We have no doubt that an earnest effort was made to check the possibility of previous hemorrhage, but it is conceivable that some

of these patients may have had previous episodes of bleeding not revealed in their histories. We examined our own cases from this standpoint and were surprised to find that as many as 55 per cent gave no previous history of hemorrhage. Let us accept the statistical conclusions arrived at by the authors. If, in addition, we assume that early operative intervention in the older group is attended by a mortality appreciably less than the 30 per cent apparently obtained with medical treatment in this group, we must inevitably conclude that massive first hemorrhage in older individuals demands immediate surgery. We are reluctant to follow this reasoning to such a conclusion. The patient's age and the fact that it is his first bleeding episode are insufficient indications, in any one case, that death will ensue. The problem still remains to determine early which patients are likely to die. We feel that there are no satisfactory early criteria. By the time the clinical picture indicates the probable fatal outcome, it is usually too late for successful surgery.

DR. IRVING GRAY, Brooklyn: In 1931 Cushing reported that following the injection of solution of posterior pituitary and pilocarpine into the lateral ventricle in man there was increase in gastric tonus, hypermotility and hypersecretion. The following year he reported a series of cases in which there occurred acute perforation of the esophagus, stomach and duodenum responsible for death from one to four days after operation on the brain for the removal of tumors. He presented evidence in support of the existence of a parasympathetic center in the hypothalamus which sends fibers to the medullary vagus center. Beattie, Masten and Bunts, Keller, and Holler and Pollack have made contributions which point to the existence of a parasympathetic center situated in the hypothalamus which sends impulses downward to the medullary vagus centers. Drs. Boles and Riggs have pointed out that the acute gastric ulceration in their series shows (1) no essential pathologic difference between these lesions and the acute gastric ulcer found in the absence of such disease, that (2) the mucosa lesion is the result of an acute phase of gastric circulatory deficiency of a prolonged type and that (3) pathologic alterations in other viscera in these cases demonstrate that the so-called neurogenic ulcer is not a primary isolated phenomenon but a focal manifestation of a generalized circulatory insufficiency. In view of these observations, which indicate that the so-called neurogenic ulcer is not an isolated phenomenon in the stomach but an expression of generalized circulatory insufficiency, it might be reasonably assumed that a variety of cerebral pathologic conditions may lead to the production of focal areas of vascular disturbances. Whether or not alterations in function of the parasympathetic center in the hypothalamus are the cause of focal vascular disturbances in the stomach and elsewhere is an important question. One may ask whether a chronic ulcer of the stomach may not have its original inception through some disturbance of the vegetative centers. Can an acute gastric ulcer follow as a result of emotional disturbances which are usually expressed through the autonomic nervous system? Will continuous imbalance of the two major divisions of the autonomic nervous system cause gastric ulceration of a chronic nature? The psychoanalytic school has repeatedly called attention to the improvement which follows psychotherapy in patients who have gastrointestinal disorders, including peptic ulcers. We have all long recognized the importance of the autonomic nervous system in the treatment of patients with chronic peptic ulcer.

DR. BURRILL B. CROHN, New York: Drs. Blackford and Williams have helped to classify the statistics of hemorrhage. In past years hemorrhage was spoken of without analysis of age incidence, sex or complicating factors and without differentiating mild from severe hemorrhage. A first severe hemorrhage may arise from carcinoma; if a first hemorrhage is fatal, the chances favor carcinoma. Secondary hemorrhages are more likely to be benign and are usually less severe. I have not yet met a surgeon who in this country has operated in a case of ulcer hemorrhage in the first twenty-four hours of a severe hemorrhage. Finsterer has formulated his surgical approach: he employs infiltration anesthesia of the abdominal wall, the patient being operated on within the first twenty-four hours, but there is no clear concept of what exactly should be

done. In some cases he uses tamponade against the side of the ulcer, in others he ties off the vessels and in still other cases he resects with exclusion of the duodenum. If one is going to undertake a program of operations for hemorrhage within the first twenty-four hours, one should approach the problem with some sort of understanding of its real significance, risks, mortality and curability.

DR. ANDREW B. RIVERS, Rochester, Minn.: The work of Drs. Blackford and Williams regarding the grave threat to life of massive hemorrhages beyond 45 has borne abundant fruit. They have made all of us more cautious in the handling of these patients. The additional attention lavished on older patients with gastric hemorrhages has saved many lives. I will not quibble about their statistics. I do not quite share their apprehension regarding the danger to life of gross gastric hemorrhage in the younger section of the 45 years and older group, but let's assume that in the older group the proportion of fatalities is about 30 per cent; we are called out to see an old fellow who has just had a massive hemorrhage. The authors have shown us that more often the first hemorrhage is likely to be the fatal one. The diagnosis therefore may be unsettled. The patient may be in shock. His condition is critical. How shall one know whether this patient should be subjected to surgical treatment? Drs. Blackford and Williams believe that the more serious the hemorrhage the more necessary it is to operate on this patient promptly. We have been taught that he has something like a 70 per cent chance of survival if not operated on. If we inveigle a surgeon into a laparotomy, a number of the 70 per cent who would survive otherwise will not then be so fortunate. In my experience it has often been impossible to determine the gravity of the patient's condition for the first twenty-four hours following a gastric hemorrhage. The continuation and recurrence of bleeding or the development of other complications has usually decided the outcome. But granted that our impressions regarding the diagnosis and the extreme gravity of the condition are correct, there is always the probability that such a patient will not survive surgical treatment. Theoretically it sounds simple to clamp a spurting vessel and stop it from bleeding, but actually surgical procedures under such conditions are usually complex and difficult. These deliberations are of vital importance. Our responsibility in these matters is a serious duty. All practitioners of medicine must be made to realize the serious threat to life of a massive hemorrhage in an elderly patient, but do we want them to believe that the treatment of choice under these circumstances is to subject their patients to surgery? If I at 60 was to have a gross stomach hemorrhage and was removed some distance from an expert gastric surgeon, I would rather stake my chance of survival on an ice pack, a hypodermic or two, and a couple of transfusions. Drs. Blackford and Williams have done a fine piece of work by teaching the profession that a gastric hemorrhage in an elderly patient is a complication which requires most careful attention. I believe, however, that conscientiously applied nonsurgical means would ordinarily result in fewer fatalities than would the precipitous employment of operative methods.

DR. HYMAN I. GOLDSTEIN, Camden, N. J.: It is of interest to note with regard to the presentation by Boles and Riggs on "Neurogenic Factors" the publications on the "Hypothalamus" by Haymaker and Anderson (*Internat. Clin.*, June 1940, pp. 226 and 253) and Donald Sheehan ("The Hypothalamus and Gastrointestinal Regulation," 1940). Contributions have been made to our knowledge of such relationship by Schiff (1867), Ebstein (1874), Durante (1916), Brown-Séquard (1876), Pomorski (1892), Keppich (1921), Stahnke (1924), Mogilnitzky (1925), Korsts (1828), Cushing (1932) and others. Frerichs produced ulcer of the stomach in a cat after division of the splanchnic nerves and of the celiac axis. Ebstein, by injuries to the brain and cord in animals, produced ulcers on a hemorrhagic base. Articles by Master and Bunts (1934) and Vonderahe (May 1939) are of interest. William Fabricius Hildanus (1560-1634) knew of the relationship of the brain and gastrointestinal disturbances (*Opera Observationum et Curationum, Francofurti, 1646*)! Several questions might well be put to the authors. Why do young infants get ulcer even without hyperacidity? Bird's patient had normal gastric secre-

tion. Why are so many people with hyperacidity free from ulcer? Why do ulcers occur so frequently in the duodenum with an essentially alkaline secretion? Why do ulcers continue to heal, even in the presence of hyperacidity? Why the not uncommon occurrence of ulcer following extensive burns or some surgical (abdominal) operation? Why do ulcers apparently heal spontaneously in women during pregnancy? Since Celsus (20 A. D.), Aëtius Amidenus (502-575 A. D.), Avicenna (908-1036), Laurentius Phrysen (Fries, 1518), Rembert Dodonaeus (1517-1580), Felix Plater (1534-1614), Marcellus Donatus (1586), Schenck (1595), Forestus (1594) and Jacopo Penada (1793) discussed ulcer of the stomach and duodenum, we have had the problem, still unsolved, of the etiology of peptic ulcer. Let us hope as the result of such work as reported today that a solution to this problem will be found.

DR. ANTHONY BASSLER, New York: I want to express my admiration to Drs. Blackford and Williams for their work in helping to elucidate a difficult question. Those who have to do with the hospital service in the city of New York have a real problem in this question. We have about a thousand deaths in New York from hematemesis, and among the hospitals to which I belong we have about eighty in a year. I should like to say that when a patient is brought in in extreme condition our attitude is one of rest and large doses of morphine and watching, and from then if after about six hours we are not satisfied with the clinical condition of the patient, we pass a tube in the stomach and drain it and we can get a better idea whether the bleeding is continuing than by any other method we have tried so far. I know about the high protein method. If right away we come to the idea that there is probably a pyloric obstruction present, for whatever reason, that case should be considered surgical at once, because our experience has been that these patients die if they have a pyloric obstruction; so that when from the twelfth to the forty-eighth hour there is a continuation of bleeding, dripping from the tube, and particularly if it is of a serosanguineous character, we are very prone to consider that case as surgical within the forty-eighth hour and try not to wait until a full four days has passed, because, if these patients are operated on after the full four days after a massive hemorrhage, they almost invariably die.

DR. HORACE W. SOPER, St. Louis: In 1931 I reported my method of treatment of massive hemorrhage from the stomach by the introduction of the Levine duodenal gastric catheter, thoroughly lavaging the stomach, breaking up the clot, leaving the catheter in place, and employing siphonage. Ordinarily one will get some mucus and small blood clots which may be seen in the glass connecting tube which leads to the container on the floor. Bright red blood in the tube indicates arterial hemorrhage, which of course calls for immediate surgical procedure. In my experience the surgeon has always been able to locate the spurter, ligate it and save the patient.

DR. FREDERICK W. MULSOW, Cedar Rapids, Iowa: I have been making similar studies from death certificates and doctors' records in Cedar Rapids in the last eight years, and during that period we have had sixty-five deaths proved due to peptic ulcer. One difference, apparently, from other records is the number of deaths among women. Of the sixty-five deaths, twenty-three were of women. One other factor, as Drs. Blackford and Williams mentioned, is that death is much more common among older persons. Of those over 50 years of age there were forty-two deaths—about two thirds. Among those over 60 years of age, twelve deaths were due to hemorrhage, eight to perforation and five to obstruction, with surgical operation. Young persons, of course, showed a much higher rate of perforation as the cause of death.

DR. RUSSELL S. BOLES, Philadelphia: Dr. Palmer states that it might be well not to assume that our observations on acute ulceration were directly traceable to the sequence of events we described; that perhaps it would be better to think of the ulcers having occurred incidentally. We cannot agree with Dr. Palmer that the ulcers were incidental for a number of reasons. First I would refer him to the original observations of Cushing, who reported a group of cases in which perforation of acute ulcers occurred following operation for brain

tumor. Surely the acute ulcerations and perforations described by Cushing were not merely incidental to his operations. I would refer Dr. Palmer to the original research work of Drs. Klemperer, Penner and Bernheim which they reported last Monday before the American Gastro-Enterological Association. As a result of prolonged administration of epinephrine intraperitoneally they produced acute ulcers of the stomach which obviously were not incidental but the result of the administration of the epinephrine. Ulcers which occur as a result of experimental production of hypoglycemia, which it is known stimulates the hypothalamic centers, cannot be regarded as incidental. The acute ulcers produced by Hoff and Sheehan and others in the rhesus monkey as a result of irritation of the hypothalamic centers would not seem to be incidental. Last year Dr. Necheles reported before the American Gastro-Enterological Association the occurrence of acute ulceration of the stomach following the ligation of certain blood vessels and this would appear to be experimental confirmation again of our observations. Finally, I would refer Dr. Palmer to the investigative work of Nedzel, who by means of experimental pitressin episodes brought about the production of acute hemorrhagic conditions and acute ulceration of the stomach which definitely were not incidental. For these reasons I believe we are justified in assuming that there is a correlation in the pathologic conditions we have reported and that the ulcers we observed were not purely incidental but were dependent for their production on the associated neurogenic conditions. I am going to request permission for Dr. Riggs to answer the one remaining question about the pathologic changes we have described. I should like to emphasize that our conclusions have been based on the study of a large group of cases by an experienced neuropathologist. For the past five years Dr. Riggs has examined sections of the stomach in every case in which the brain has been removed. This constitutes more than 1,500 cases.

DR. HELENA E. RIGGS, Philadelphia: Dr. Palmer's suggestion that the changes we have demonstrated in the viscera in our cases are due to the agonal state rather than to chronic circulatory insufficiency is rather disturbing to a pathologist. Since the time of Virchow the pathologist has considered an increase of interstitial connective tissue associated with loss of parenchymatous elements as characteristic of chronic passive congestion, i. e. chronic circulatory insufficiency. The very nature of such tissue alterations precludes the possibility of their occurrence in the last few hours before death. As for the gastric mucosal lesion, we have stated that this is acute and therefore must be considered as occurring in the agonal period. However, we do not believe that the mucosal lesion alone constitutes a gastric ulcer. On the basis of experimental and gastroscopic studies, and of our own postmortem examinations, we feel that an acute ulcer is the result of persistent or recurrent alterations in circulatory efficiency to focal areas of the entire gastric wall. In the deep layers this results in chronic degenerative changes; in the mucosa—which has greater regenerative powers—in cyclic destruction and regeneration. Eventually, as we have attempted to demonstrate in our slides, the mucosa fails to regenerate and the acute phase of gastric ulceration passes into the chronic stage. Dr. Palmer has also suggested that the presence of acute gastric lesions in cases of primary intracerebral disease is merely incidental or, at most, associated with terminal failure of circulation. It will be seen from our charts, however, that such gastric lesions occur in cases of primary cerebral disease with a frequency which is statistically significant. Further, it is our experience that in such cases clinical symptoms of acute gastric ulcer, such as melena or blood stained vomitus, frequently occur. As to the effect of circulatory insufficiency on the vegetative nervous system, we have been able to demonstrate clinical signs of vegetative stimulation, such as pupillary changes, pulmonary edema and rapid pulse, in many of the cases which at postmortem showed acute gastric ulcers based on circulatory insufficiency.

DR. JOHN M. BLACKFORD, Seattle: With regard to the mortality rate of 30 per cent, I would emphasize that this represents in our series approximately the mortality of the more serious hemorrhages. Serious hemorrhage was noted in approx-

imately half of all who bled in the older group. I think this is very important because when mortality rates are quoted as only 9, 10 and 15 per cent they are based on hospital admissions with gross hemorrhage at all ages, and that is not the basis of our report of a 30 per cent mortality rate. Dr. Allen's work and our own has emphasized that those are critical hemorrhages which present evidence of great loss of blood and shock and all that goes with it. I want to agree with Dr. Rivers, but if I were in a remote part of the world, with no competent surgeon available and I suffered a gastric hemorrhage, I would not be operated on; however it does seem to me that, if this risk of 30 per cent from serious hemorrhage which is agreed on by a number of men besides myself is correct, then probably the surgeon should be able to work out some method of stopping the hemorrhage, because only in that way can these lives be saved.

RECURRENT PEPTIC ULCER

SITUATION OF RECURRENCES AND THE IMPORTANCE OF STUDIES OF PAIN IN THE RECOGNITION OF SUCH RECURRENCES

ANDREW B. RIVERS, M.D.

AND

JOHN W. GARDNER, M.D.

Fellow in Medicine, the Mayo Foundation
ROCHESTER, MINN.

Peptic ulcer is among the most frequent of the organic causes of gastronomic unhappiness, and pain is the most consistent among the complaints of patients who have this disease. Not only is the proper evaluation of pain important in the recognition of peptic ulcerative disease, but much regarding the histopathologic condition of such a lesion can be determined by a critical study of the type, situation and reference of the pain present. Although there is a fairly consistent reduplication of characteristics in the symptomatology of peptic ulcer, there is nevertheless considerable variability in the complaints which patients who have this disease will volunteer. This variability seems reasonable when it is considered that, as peptic ulcer invades successive depths of tissue, definite changes in symptomatology may well occur. As neighboring organs are involved and as normal physiologic processes become increasingly disturbed, symptoms might well arise which would substitute for or complicate a syndrome already established by an original, uncomplicated lesion.

PURPOSE OF THE STUDY

Previously, one of us¹ reported a study of pain caused by ulcers situated in different portions of the gastrointestinal tract. In this study the varying states of pathologic development, as ascertained at operation, were correlated with the symptoms of which the patient had complained immediately prior to laparotomy. Thus, by comparing a sufficient number of such accurately allocated lesions with the symptoms they produced, it was believed that a type of serial-section picture could be constructed which might permit correlation between the various changes of the histopathologic life cycle of ulcer and the changing, painful experiences noted by patients who had such a lesion. It was noted that ulcers which penetrated deeply into the tissues produced shifts of the original pain into secondary regions. In such instances much of the symptom complex set in motion by the previously uncomplicated peptic ulcer was lost.

By studying with sufficient thoroughness the exact situation of the pain and the course over which it was projected, as well as the behavior of the symptoms caused by lesions in various situations and at varying depths of tissue, it was believed that certain information might become available by means of which the anatomic and physiologic problems of abdominal pain and its pathways of conduction could be better understood. In this paper we hope to extend this information by means of an examination of the more common localizations of secondary ulceration following various surgical procedures, and by a discussion of the pain they produce.

PATHWAYS AND MECHANICS OF PAIN

There are three important pathways over which painful impulses originating in peptic ulcer can reach the patient's consciousness:

1. The pathway most commonly used for pain produced in uncomplicated peptic ulcers is probably that which involves the visceral splanchnic nerves. The impulses originate in the wall of the gastrointestinal tract, course along sensory bundles in the sheaths of the splanchnic nerves, cross over through the white rami communicantes of the thoracic nerves and pass along the posterior roots of the spinal nerves, thus reaching the posterior horn of the spinal cord. This type of pain has a quality peculiar to itself. It is usually a rather diffuse type of pain, poorly localized, frequently associated with flatulence and usually not very severe, although at times it may be rather acute and colicky. It is dissipated quickly at times, leaving but little residual soreness and tenderness. Seldom is rigidity of the abdominal muscles associated with such pain, and cutaneous hyperalgesia is usually absent. To explain the genesis of pain arising from viscera which ordinarily seem practically insensitive to the stimuli which produce pain on the surface of the body, the presence of an "adequate stimulus" must be postulated. This "adequate stimulus" has been assumed to be an increase in pressure within the gastrointestinal segments which results in stretching of the circulatory fibers of the viscus. We have reason to believe that this mechanism is not so much one of stretching but rather one of "contracting resistance" of the hardy muscular fibers, as marked distention of circular organs which have lost their muscular contractility frequently produced no splanchnic type of pain. It has been suggested that in the stomach this spasm can be the result of hyperacidity, which acts as a trigger mechanism for the production of such spasm. The ordinary uncomplicated syndrome of peptic ulcer with its recurring painful phenomena, dissipated by food and soda, is probably illustrative of this type of pain-producing mechanism, interpreted along the splanchnic pathway.

2. The varying shifts of pain into secondary regions that occur when the ulcer in its progression begins to venture beyond the confines of the bowel can probably be explained more satisfactorily on the assumption of the existence of a second pathway which supplements the originally utilized splanchnic routes. Painful impulses, it will be remembered, may also be conducted from tissues surrounding the wall of the bowel to the spinal cord over the sensitive cerebrospinal nerves, twigs of which supply the parietal peritoneum and mesentery. This route is designated as the spinal-sensory-somatic pathway.

The shifting type of distress caused by a perforating ulcer is a "referred pain." When the ulcer, because of

its progression, makes contact with tissues supplied by spinal-sensory nerves, pain may be interpreted as being felt along the peripheral cutaneous, more highly differentiating, branches of these same nerves, such as the intercostal nerves.

In a series of ulcers studied by one of us¹ it was found that duodenal ulcers with perforating characteristics produced a shift of pain from the original region to the right upper quadrant of the abdomen and right side of the back. Gastric ulcers so complicated produced a shift of pain toward the left upper abdominal quadrant and the left portions of the thorax and back, whereas perforating gastrojejunal ulcers almost always produced definite shifts of pain downward or through to the back. Such shifts of pain all conform fairly well to peripheral regions supplied by somatic branches that could be expected to be invaded by penetration of such lesions.

3. There seems little doubt at the present time that painful impulses originating in the cardiac portion of the stomach may reach the spinal cord over the phrenic nerves. This pathway is probably utilized rarely, except by perforating lesions invading the diaphragm. One of the most conclusive indications of this pathway is demonstrable in the following report:

A man aged 26 entered the Mayo Clinic complaining of indigestion and pain in the tip of the left shoulder which extended into the base of the neck. This pain arose several hours after meals, and was relieved by eating. Ten years previously gastro-enterostomy had been performed elsewhere because of perforating gastric ulcer. Roentgenograms revealed a deformity high in the stomach. At operation the patient was found to have what appeared to be a perforating gastric ulcer, which had

The phrenic nerve arises mainly from the fourth cervical segment, and to some extent from the third and fifth cervical segments, of the spinal cord. After passing through the thorax it supplies motor fibers to the diaphragm and also supplies sensory fibers to the

Fig. 2.—Situation of ulcers and direction of the shifts in pain therefrom following sleeve resection.

Fig. 1.—Situation of ulcers and direction of the shift in pain therefrom in the case of simple excision.

become adherent to the diaphragm and spleen. Excision of the ulcer was not possible and, as the gastro-enteric stoma was functioning normally, no further surgical procedure was undertaken at that time. The pain in the tip of the shoulder persisted and two weeks following this operation left phrenic emphysema was performed, a procedure which completely relieved the pain in the shoulder and neck.

diaphragmatic pleura as well as to the peritoneum, lining the under surface of the diaphragm. Originating in the same segments of the cord as the phrenic nerve are the suprascapular, supraclavicular and supra-acromial nerves, which are involved in the production of pain in the tip of the shoulder. These nerves may thus be regarded morphologically as the superficial cutaneous branches of the phrenic nerve.

To explain the mechanism of such referred pain, various theories have been advanced. In discussing this, Mackenzie² has the following to offer: "One very attractive explanation is supplied by Ross's³ theory of an 'irritable focus' in the spinal cord." Applying this theory to pain in the tip of the shoulder, it would be supposed that the painful stimuli passing up the phrenic nerves to the third, fourth and fifth cervical segments of the spinal cord produce an irritable focus in the corresponding portion of the posterior horns of gray matter.

Because of this state of irritation, a lowering of the threshold of the cells of the posterior horn results and the consequence is that the stream of afferent stimuli from the cutaneous nerves entering the same segments, although normally silent and unobserved, now becomes capable of producing pain.

Occasionally, pain in the tip of the shoulder is noted on the right side following perforation of a duodenal

ulcer, an occurrence which Morley⁴ assumes is the result of contact of the irritating fluid with the sensitive under surface of the right portion of the diaphragm. In perforation of a high lying gastric ulcer, pain, if present, is situated usually on the left side.

MATERIAL FOR STUDY

This study includes sixty-five cases of postoperative recurring ulcerations. The exact situation of both primary and secondary lesions was ascertained by roentgenographic evidence. The situation of the secondary ulcerations was confirmed by direct inspection of the tissues at operation. Only those cases were accepted for study which had a history that included exact information regarding the syndrome under consideration.

An inquiry was made as to the situation, duration and character of the pain, the time of its onset and the mode of relief. A special attempt was made to compare the characteristics of the original lesion with those of the one which developed postoperatively. Ten types of operative procedure are included in this group. Each type is illustrated by an illustration (figs. 1 to 10) in which are placed the situations of the primary and secondary ulcerations, together with the situations and extensions of the pain which they produce. Circles indicate lesions of the anterior gastric or intestinal wall and dots indicate ulcers of the posterior wall. Each dot indicates one case and the situation of maximal distress. The arrows indicate the direction of the shifting pain (fig. 1).

Recurring Gastric Ulcer Following Excision.—Occasionally, during surgical procedures undertaken to cure

Fig. 3.—Situation of ulcers and direction of the shifts in pain following performance of the Judd type of excision and pyloroplasty.

a gastric ulcer, it is found that the lesion is small and that it will lend itself easily to excision. Unless excision of the ulcer is rather extensive or unless excision with gastro-enterostomy is performed, there is a tendency

for such lesions to recur. If this occurs, the resulting ulceration usually develops in immediate contiguity to, and more often on the pyloric side, of the suture line. The diagnosis of recurring ulcer is usually made without difficulty. Even though there is no distinct roent-

Fig. 4.—Situation of ulcers and direction of the shifts of pain following performance of the Judd type of gastroduodenostomy.

genographic evidence of a lesion, the history of recurring difficulties with pain localized in the region of pre-operative complaint, usually mimicking in almost every detail the original symptoms, is sufficient to make the diagnosis. There is a tendency for these lesions to penetrate, particularly into the pancreas. There is a notorious lack of periodicity in the syndrome of the secondary ulceration, the distress being present almost daily. There is also less tendency to relief by the ingestion of food and alkali (fig. 2).

Recurring Ulcer Following Sleeve Resection.—Several years ago it was not uncommon for surgeons to perform resection of a segment of stomach in which a gastric ulcer was situated and then restore the continuity by end-to-end anastomosis. Other surgical procedures are now employed, and they are so much more successful in dealing with gastric ulcers that sleeve resection is now seldom used. It was found that following the sleeve type of procedure mechanical difficulties developed, resulting in disturbed function of the stomach; furthermore, there was a high incidence of recurring ulceration. Additionally, coexisting duodenal ulcers were not infrequently overlooked during such operations, and consequently, postoperative difficulties were very common. The situation of recurring ulceration following sleeve resection was found to be in or immediately below the suture line. Occasionally, recurrence would take place a short distance above the site of anastomosis. The type of pain caused by primary and secondary ulcers was very similar, although in the latter instance the pain was somewhat more severe than that caused by primary ulcers, with a tendency to shift into the left side of the thorax, a circumstance probably referable to the fact that most of the recurring ulcers were of the perforating type. Again, relief afforded by

⁴ Morley, John: *Abdominal Pain*, Edinburgh, E. and S. Livingstone, 1931.

ingestion of food and soda was not so complete as it had been before the operation for primary ulcers (fig. 3).

Recurring Ulcer Following the Judd Type of Excision and Pyloroplasty.—Judd pointed out that there are certain cases of duodenal ulcer on the anterior wall

was similar to that of the primary lesion. Again, the pain of the recurring lesion proved to be somewhat more constant and intractable than that of the original ulcer. In most instances there was also some mechanical disturbance resulting in a moderate amount of gastric retention.

Recurring Duodenal Ulcer Following the Finney Type of Pyloroplasty.—In figure 5 is illustrated the type of operation devised by Finney for reconstruction of the pyloric outlet, dealing directly with the ulcer and yet achieving adequate anastomosis between the stomach and the duodenum. In some instances this operation was followed by good results and in others by mechanical difficulties; in still another group recurrences of ulcers took place, usually in the vicinity of the anastomosis or slightly below the suture line. Occasionally a second ulcer was found, lower in the duodenum. The situation and symptoms of recurring ulcer following this type of surgical procedure are usually very similar to those experienced at the time of the original ulcer. The region of distress is close to the costal margin, slightly lower than that caused by acute cholecystic disease. Additionally there are the usual signs of organic disturbance and deficiency in gastric emptying, which probably contribute to the inadequacy of relief achieved by the ingestion of food and soda as compared to relief achieved by the same measures directed against the primary lesion.

Recurring Ulcer Following the Billroth I Type of Anastomosis.—This type of Billroth operation has many modifications. However, the principle of these is essentially the same. It consists in removal of the lesion and

in which excision and reconstruction of the pyloric outlet are followed by excellent results. This operation was most commonly employed for young patients who had nonobstructing ulcer in whom there was marked hyperacidity and a small, high lying, hypertonic stomach. The incidence of recurrence, in this group, was rather high. Such recurrences usually developed in the posterior duodenal wall slightly distal to the incision, although occasional recurrences were found in the anterior wall. Unless careful exploration revealed that there was no coexisting ulcer in the posterior duodenal wall, recurring difficulties might rapidly develop from an overlooked lesion on the posterior wall. The symptom complex of these recurring ulcerations was slightly more severe than that caused by the primary lesion. The situation of the pain was similar, with more tendency to extend into the right side of the thorax or back, as is indicated in figure 3. Relief from the pain afforded by ingestion of food and alkali was less marked.

Recurring Ulcer Following Judd Type of Gastro-duodenostomy.—There are certain instances in which anastomosis of the stomach to the uninvolved portion of the duodenum, circumventing the pylorus and the lesion, has been utilized with some success in the treatment of these conditions (fig. 4). The region of the ulcer is avoided and the anastomosis is made entirely in healthy tissue. Although the results of this operation were sometimes good, recurring ulcer not infrequently developed. Such recurrences were found in the duodenum and in many instances were thought to be merely a reactivation of the original ulcer which had failed to heal. The situation of secondary complaints

Fig. 5.—Situation of ulcers and direction of the shift in pain following performance of the Finney type of pyloroplasty.

Fig. 6.—Situation of the ulcers and direction of the shifts in pain following performance of the Billroth I type of anastomosis.

the restoration of the gastrointestinal continuity in an end-to-end anastomosis (fig. 6). Some of the patients so treated remained well but recurrences sometimes took place, invariably appearing in the vicinity of the site of anastomosis, usually immediately below the suture line. The marginal ulcer which developed in many of these

patients was often extensive and was complicated not infrequently by hemorrhage or deep penetration. The situation of the original distress was usually definitely to the right of the midline, frequently with reference of pain into the right side of the thorax and back. Recur-

Fig. 7.—Situation of the ulcers and direction of the shifts in pain after posterior gastro-enterostomy for peptic ulcer.

ring ulcers exhibited characteristics almost identical to those for which the operation had been performed. Mechanical difficulties seldom occurred.

Stomal Ulcers Following Posterior Gastro-Enterostomy.—Posterior gastro-enterostomy still remains the operation of choice in many instances of peptic ulcer. A stoma which is properly placed and which is of proper dimensions aids in the adequate emptying of the stomach (fig. 7). The chemical response within the stomach is usually favorable, so that recurring ulceration rarely takes place. Occasionally, however, this type of operation is followed by results which are not entirely satisfactory. The original ulcer in the duodenum may fail to heal, in which instance there is a recurrence of the original symptoms. The distress is then localized above the umbilicus and to the right of the midline.

In figure 7 we have indicated the situation in which secondary ulcerations occur. Most frequently the ulcer is found just distal to the site of anastomosis, often invading the stoma. Next in frequency are ulcers which are definitely jejunal and are found distal to, or opposite, the site of anastomosis. Rarely does the ulcer develop in the proximal loop just above the gastro-enteric stoma. The symptoms of stomal ulcer are similar to those caused by duodenal or gastric ulcer. In most instances these ulcers are of the penetrating type, and consequently there is less periodicity and less tendency toward remission of symptoms. The pain which develops is poorly defined and poorly localized and often is associated with a sense of intestinal unrest which occurs an hour after the meal. Prior to the

development of the pain there is frequently evidence of transitory retention, during which there is loss of appetite, nausea and a vague sense of hypogastric fullness. The situation of pain in uncomplicated gastro-jejunal ulcer is usually to the left and slightly above the umbilicus. If penetration takes place, involving the mesenteric side of the organ, there is almost invariably a shift of pain downward to the left and toward the left iliac region. Less frequently it is found in the right iliac or lumbar regions. Occasionally the pain extends into the scrotal region. Extension to the back of pain caused by penetrating jejunal ulcer is usually definitely lower than that experienced with the original lesion.

Stomal Ulcers Following the Devine Type of Antral Exclusion Operation.—This operation is based on the presumption that the most certain indirect means of obtaining a cure of duodenal ulcer is by excluding it from the irritation of all food and gastric secretion. This type of surgical procedure is illustrated in figure 8. In some instances, however, difficulties arose, as not all the acid-bearing portion of the stomach was excluded by the operation and the duodenal ulcer failed to heal. More often recurring difficulties resulted from the development of stomal ulcers involving the anastomosis or approximating it on either the gastric or the jejunal side. The symptomatology of recurring ulceration had characteristics simulating those for which the operation had been performed, although the situation of the distress was usually farther to the left than that caused by the original lesion. A majority of the recurrences were perforating in type, and in these, especially when

Fig. 8.—Situation of ulcers and direction of the shifts in pain after the Devine type of antral exclusion operation.

they were jejunal in situation, there was a shift of pain into the left iliac region.

Stomal Ulcers Following the Billroth II Type of Anastomosis.—The principle of this Billroth II anastomosis is similar to that of the Devine operation, but a posterior side-to-side anastomosis is made. Occasionally, following this type of surgical treatment, ulcer

developed around the gastro-enteric stoma, as is indicated in figure 9. In one instance an ulcer recurring after this type of operation was gastric in situation. This ulcer may have been overlooked at the time of the operation. In some cases ulceration may have taken

and is somewhat relieved by food or soda. This may be caused by shallow gastric ulcers accompanying a post-operative gastritis.

COMMENT

In evaluating the complaints of the patient who has been operated on previously for peptic ulcer in order to treat such a patient for recurrent ulcers, it is important for the physician to have accurate information regarding the type of surgical procedure which was performed. It is also advantageous for him to be acquainted with the details of the preoperative complaints. A duodenal deformity does not imply that an active duodenal ulcer is present and the persistence of symptoms following operation which were not caused by ulcer would be the rule rather than the exception in such a circumstance. If, on the other hand, symptoms obviously referable to ulcer persist following an operation, it is safe to assume that the original ulcer is not healing or that a second ulcer was present at operation and was not discovered. If scrutiny of preoperative complaints reveals the fact that there was localized distress in two definitely separated regions, for instance, one to the right and slightly above the umbilicus and the other approximating the left costal margin, and if surgical attention had been directed toward only one lesion, persisting symptoms in one of these regions are almost certain to indicate an overlooked ulcer. Persistence of distress in the upper right abdominal quadrant, with characteristics of ulcer following an operation during which an anterior duodenal ulcer had been excised or pyloroplasty performed, indicates with accuracy that a second ulcer, probably on the posterior duodenal wall, was not discovered by the surgeon. If, following an operation performed for an active peptic

Fig. 9.—Situation of the ulcers and direction of the shifts in pain after performance of the Billroth II type of anastomosis.

place in the jejunal or immediately above the gastro-intestinal stoma. Situation of the pain of these recurring lesions was usually to the left of that caused by the original ulcer and was usually above the umbilicus, when the ulcer involved both gastric and jejunal segments. When the ulcer was found to have involved jejunal segments alone, the pain was usually indicated as being at the level of, or below, the umbilicus. Again, the majority of these lesions were of the perforating type and under such circumstances produced a shift of pain downward toward the left iliac region.

Stomal Ulcers Following Resection and Polya Type of Anastomosis.—Although recurring ulceration following partial gastrectomy with a Polya type of anastomosis (fig. 10) is not a common occurrence, nevertheless it does happen sufficiently often that it must be considered in evaluating the symptomatology of patients who present themselves with recurring difficulties following this type of surgical procedure. The patients included in the present study all had duodenal ulcers as the original lesion. Recurring ulcerations such as these usually involve the site of anastomosis or are found near it. Occasionally the recurrence takes place below the site of anastomosis or, rarely, on its gastric side. The pain of which the patients complain is situated to the left and below that caused by the original lesion. In most instances these ulcers perforate more deeply than did the original ulcers, so that the symptoms they produce are more severe and more intractable to measures for obtaining relief than were those of the original lesions. At times a poorly localizable pain persists or develops following other types of operation; it is localized in the left upper abdominal quadrant. This distress reaches its maximum several hours after meals

Fig. 10.—Situation of the ulcers and direction of the shifts in pain after performance of resection and a Polya type of anastomosis.

ulcer, the patient enjoys a comfortable period subsequent to which symptoms characteristic of ulcer again result, it remains only to determine where more ulceration has occurred. The situation of the distress and its coincidence with the preoperative region of complaint now becomes important. If the original ulcer was

duodenal and if the region of distress was localized to the right and slightly above the umbilicus, and if the recurring distress conforms in situation to this region, the recurring cause of the complaint is again likely to be duodenal. In the event that the original ulcer was gastric in situation, a recurring ulcer in the same situation would almost invariably cause the reappearance of the complaints which accompanied the original lesion. This is very definitely true if, with the original ulcer, there had been a shifting of pain into secondary regions and if the recurring syndrome included an identical shift of the pain. Roentgenologic investigation remains of paramount importance in the recognition of secondary or recurring ulcers. There are times, however, when accurate and critical studies of situation, type and reference of pain caused by such lesions furnish more accurate information regarding their situation and histopathologic condition than is possible by any other means except direct inspection of tissues.

The closer the recurring ulcer is to the original lesion, the more nearly identical will be the recurring syndrome to the original syndrome. When operations are performed which permanently drain an acid chyme on jejunal mucosa, ulceration occasionally develops in the gastro-enteric stoma or in the jejunal segment contiguous to the new opening. More often this erosion occurs in the path of the draining chyme below the site of the stoma.

If the ulceration occurs at the site of anastomosis, both gastric and jejunal segments may be involved equally, resulting in pain which, although it is situated farther to the left than it would be if the original lesion had been duodenal in situation, is no lower than that experienced by the patient prior to the operation. Should the ulcer, however, develop in the jejunal segment, the situation of the resultant distress usually is in a lower region. When such an ulcer deeply invades tissues, projecting its inflammatory reactions to tissues surrounding the bowel, a secondary shift of pain occurs which is usually definitely lower in situation than the original distress.

The general character of the symptoms produced by the secondary ulcer is similar to that of the first. The pain caused by a shallow peptic lesion is usually difficult to localize unless it produces mechanical disturbances, and this is true regardless of the position of such a lesion. It may produce no pain at all.

A majority of secondary ulcerations, however, tend to penetrate the tissues, and when the deeper tissues of a viscus are invaded there is a tendency for the syndrome to become more definite. The region of pain can usually be indicated with fair precision. With the onset of this secondary pain, other changes in the characteristics of the syndrome experienced by these patients frequently develop. There is less tendency toward intermittence of symptoms, less relief from distress by food or alkalis, earlier onset of pain following meals, and more distress at night. Frequently abdominal tenderness becomes noticeable, and a rather persistent sensation of soreness may develop which usually is maximal over the region of pain. Often this pain does not conform to the usual sequence of pain accompanying ulcer. This is particularly noticeable when extensive inflammatory reactions pass beyond the confines of the bowel and invade tissues surrounding the viscus.

As has been indicated previously, penetration of the ulcer causes projection of pain into secondary regions. This is as true for the secondary as for the primary

lesion. The direction of pain projection depends on the situation of the secondary lesion. Thus, if the lesion is in the duodenum, it is projected into the region of the liver or right side of the back. In gastric lesions the pain is projected upward to the left side of the thorax or back. The pain of jejunal lesions is situated at about the umbilicus or slightly to the left of it and shifts downward into the left lower quadrant of the abdomen or, rarely, into the right lower abdominal quadrant.

In recurring ulceration, especially in lesions involving the stoma, more or less obstruction develops and produces distortion of the usual syndrome of ulcer. The "pain-food-ease" sequence is often lacking and the retention type of vomiting may develop. In the presence of such a complication the distress is usually indicated as diffusely spread out over the epigastrium. This is so regardless of the position of the lesion causing the obstruction.

The results of the present study of secondary ulceration tend to confirm such impressions as those which one of us (Rivers) previously expressed concerning the mechanism of the conduction of pain from peptic ulcerative lesions to the spinal cord. Uncomplicated peptic ulcer probably indicates its presence as a visceral phenomenon which asserts itself along the splanchnic nerves. Such a route, however, does not satisfactorily explain the varying shifts of pain that occur when ulcers venture beyond the confines of the bowel. These shifts of pain probably can be explained better by reference to one of the other mechanisms which we have previously discussed. Such mechanisms would include either the phrenic pathway in the case of high-lying perforating gastric lesion or a route along the sensory spinal nerves. Those nerves could be expected to produce a syndrome less rhythmic and clearcut than the syndrome caused by uncomplicated ulcer, since they are sensitive to many stimuli in addition to the "adequate stimulus" producing pain over the splanchnic route.

CONCLUSIONS

1. The situation of the majority of recurring peptic ulcerations is in or near the site of surgical anastomosis if operation has been performed. The physical factor probably determines the site at which the ulcer will develop. The situation of maximal force of impingement of the chyme decides the situation of erosion.

2. The general characteristics of the symptoms of the recurring lesions are similar to those produced by the original lesions.

3. A majority of secondary ulcerations tend to penetrate deeply and, therefore, produce symptoms which are less intermittent, cause more distress at night and are less easily relieved by food and alkali.

4. A great number of recurring lesions involve the site of surgical anastomosis with the production of more or less obstruction, which tends to distort somewhat the usual syndrome for ulcer.

5. Uncomplicated primary or secondary peptic ulcer probably indicates its presence as a visceral phenomenon, which asserts itself along the splanchnic nerves.

6. The projecting pain of perforating peptic ulcers is in all probability the result of direct stimulation of the spinal sensory nerves which produces referred pain in the distribution of the more highly differentiating peripheral or cutaneous branches of these nerves.

7. When a gastric ulcer begins to produce pain in the tip of the shoulder, indicating use of the phrenic pathway, it can be assumed that deep penetration or active perforation has occurred.

THE EFFECT OF MERSALYL (SALYRGAN) ON PLASMA VOLUME

VERNE W. SWIGERT, M.D.

EVANSTON, ILL.
AND

REGINALD FITZ, M.D.

BOSTON

In association with the diuresis obtained by mercurial diuretics in cases of congestive heart failure, two strikingly curious phenomena are often observed. Shortly after the intravenous injection of 2 cc. of salyrgan in cases responding to it there is promptly an increased excretion of water which reaches its highest point sharply and then recedes with equal suddenness. Occasional cases are encountered in which the onset of diuresis is slow and its duration longer. In general, however, the outstanding feature of the effect of such diuretics is the sharpness of the reaction and its relative shortness of duration. This fact is well demonstrated in chart 1.

Five patients with varying degrees of congestive heart failure were given by vein 2 cc. of salyrgan. They were

Chart 1.—The diuretic effect of salyrgan, expressed in rate of excretion by urine per minute during a period of several hours after the drug was injected.

asked to empty their bladders at hourly intervals thereafter and the amount of urine excreted in each instance was measured and tabulated on the basis of cubic centimeters of urine excreted per minute during the period of observation. In each instance the severity of the diuresis so induced varied though the general trend of the curve was the same. Along with the increased excretion of

water that may follow the injection of salyrgan there is also a sharp increase in the excretion of sodium chloride and to a less extent of nitrogen. The most striking clinical response to a mercurial diuretic therefore is the rapid excretion of large amounts of water and sodium chloride, which takes place during a relatively short period of time after the drug is injected.

There has been a lengthy debate concerning the precise manner in which these well known responses to the diuretic effect of mercury are brought about. When merbaphen (novasurol) first came into clinical use Saxl and Heilig,¹ Nonnenbruch,² Bohn³ and Crawford and McIntosh⁴ made observations which led them to believe that an important action of the drug was on the extra-

renal tissues and that the diuresis developed secondary to a temporary hydremia. In contrast, this idea was not accepted by Govaerts,⁵ by Christian and Bartram,⁶ by Bryan, Evans, Fulton and Stead,⁷ by Blumgart, Gilligan, Levy and Brown⁸ or by Evans and Gibson.⁹ These several investigators independently have carried out a series of ingenious experiments which were interpreted to show that the diuretic effect of mercury is due primarily to its action on the kidney, any action on the tissues and blood volume, if this exists at all, being accessory and of minor importance.

In 1937 Gibson and Evans¹⁰ described a new method for estimating plasma volume. In brief, this consists in the employment of an azo dye, "Evans blue," with the determination of its concentration in plasma by the spectrophotometer. They claim that this method is accurate, that it avoids many of the errors inherent in dye methods previously in clinical use for the determination of plasma volume and that, on the whole, it can be employed advantageously in the investigation of a variety of clinical problems. Already they and their collaborators have used this method with pertinent results in several studies.

In the fall of 1937 Dr. Gibson was kind enough to teach us the technic of this method in his laboratory at the Peter Bent Brigham Hospital in Boston. Since then at the Robert Dawson Evans Memorial about 300 plasma volume determinations have been made. In each, Gibson's technic as modified by Gibson and Evelyn¹¹ has been followed meticulously. In our hands, just as has been the experience of Gibson and his co-workers, the method has seemed reliable and has appeared to yield consistent results in different clinical states in which changes in blood volume appear to play a significant part.

It occurred to us that it would be interesting once more to investigate the effect of a mercurial diuretic like salyrgan on blood volume by the means of so accurate a clinical method for estimating blood volume as Gibson's method appears to offer. With this idea in mind seven cases have been studied, certain of them being studied repeatedly. The group included four cases with edema primarily of cardiac rather than renal origin, one case with more nearly renal edema, one normal individual, and one patient recovering from secondary anemia. The general plan of work was as follows:

Early in the morning of the experimental day the patient to be observed was treated in the following manner: A blood sample was withdrawn on which was determined the concentration of albumin and globulin in the plasma and of sodium in the serum. The concentration of chloride, of nonprotein nitrogen and of iron was determined in whole blood, and a red cell count

was made. A plasma volume determination was then performed and from it and the hematocrit reading was estimated the total blood volume. As soon as the blood necessary for this observation was obtained, 2 cc. of salyrgan was injected by vein. At various intervals up to four hours after the injection of the drug a second series of blood studies was repeated and a second plasma and blood volume determination was made. Other blood samples for chemical studies and blood counts were withdrawn at intervals during the six hour period in which most active diuresis seemed likely to occur. On the following morning a final series of blood chemical studies and a third plasma and blood volume determination was made.

The amount of urine excreted during the interval between the various bleedings was measured, as was the total volume excreted during the twenty hour cycle. The patient was allowed to eat stipulated amounts of food and to drink a measured fluid intake. The patient was weighed at the beginning of the procedure and twenty-four hours later.

The total amount in circulation of the various blood components studied was charted at different time intervals during the period of diuresis on the basis of the plasma and blood volume estimation figures, interpolations for these being made when blood samples were

withdrawn at times other than when blood volume determinations were actually made. In this manner we hoped to develop data which would tend to illustrate what happens to the composition of the blood during the period in which an active diuresis from mercury is being induced.

For technical reasons it was impossible in each case to make in perfect detail each of the observations out-

lined. The trend of our results, however, with illustrative data is reported.

Our results in relation to the plasma and blood volume following an injection of salyrgan varied, as may be seen by table 1.

There were three instances in which there was no significant change in plasma or blood volume. There were two instances in which there appeared shortly after the injection of the diuretic an initial gain in plasma and blood volume followed later by a significant loss in circulating blood. There were three instances in which, following the injection of the drug, there appeared to develop a steady and significant loss in plasma and blood volume. There were three instances in which there appeared to develop a steady and significant gain in blood and plasma volume. In brief, our results were entirely inconsistent and appeared to follow no readily comprehensible pattern. Nor is our experience unique: other workers with the problem have faced the same quandary. Brown and Rowntree,¹² studying the volume and composition of the blood by the congo red method and the changes incident to diuresis in cases of edema, found, as did we, that during diuresis changes in blood volume may occur in any direction—there may develop an increase or decrease or no change in blood and plasma volume. Fehér,¹³ making volume determinations with trypan red three hours after salyrgan injections, found at the height of the diuresis an increased volume: on the other hand, Goldhammer, Leiner and Scherf,¹⁴ making blood volume

determinations twenty-four hours after the injection of a mercurial diuretic and using both the carbon monoxide and trypan red methods, found regularly a loss in blood and plasma volume. And somewhere in between were Borruso and Ceccarelli, who, according to Goldhammer and his colleagues, found shortly after the onset of diuresis a diminished blood and plasma volume followed later by an increased volume.

The explanations given for such contradictory observations have differed widely. From the point of view of common sense the reasoning first put forth by Brown and Rowntree remains as satisfactory as any: during a sudden diuresis evanescent blood volume changes easily may take place as the result of rapid contraction or expansion of blood volume from dilution or concentration of the blood; and variable transitory adjustments in blood volume, in blood solids or fluid factors may be

relative sodium retention in comparison with the loss of chloride. There was an initial fall in plasma albumin followed by a secondary rise in spite of the fall in plasma volume. During the first few hours there was a relative rise in the plasma globulin so that for at least three hours after the drug was injected there was a reversal of the albumin-globulin ratio. Eventually this became corrected. The initial fall in chloride, sodium and globulin occurred before diuresis was established; but at the same time there was a loss of plasma volume which does not suggest an immediate mobilization of fluid into the blood stream. Rather, this isolated observation is in agreement with the view of Schmitz¹⁵ and others, who believe that the primary action of salyrgan is on the kidney with a secondary inflow of fluid from the tissue spaces to prevent excessive dehydration of the plasma.

Chart 2.—The effect of salyrgan on blood chemistry.

Chart 3.—The effect of salyrgan on blood chemistry.

Chart 4.—The effect of salyrgan on blood chemistry.

partially or completely masked by fluctuations in the water content of the blood in the absence of any demonstrable volume changes. One fact remains fairly well established: the injection of salyrgan is likely to be followed fairly promptly by significant changes in the amount of plasma and blood in circulation.

From the chemical data assembled by the methods outlined, the level of blood iron, nonprotein nitrogen and red cells showed only minor and insignificant fluctuations. These figures have been omitted as being unrevealing. The figures in relation to sodium, chloride, albumin and globulin were more noteworthy and are tabulated from three illustrative cases:

The first patient, P., a man in congestive failure, developed a loss in blood and plasma volume following the injection of the diuretic. There developed an immediate fall in blood chloride followed by a slight secondary rise and then a more marked fall as the loss in blood volume continued. There was an initial fall in the serum sodium. But later there appeared to develop a

The second patient, M., a woman with edema from a combination of myocarditis and chronic pyelonephritis, developed an increased blood and plasma volume following the injection of the diuretic. In this instance the diuresis began promptly. There was a steady increase in circulating chloride and sodium and no evidence of any relative sodium retention. There was an initial fall in the circulating albumin followed by a secondary rise: and again a transitory reversal of the albumin-globulin ratio during the period of most active diuresis.

The third patient, McM., a woman recovering from secondary anemia, developed an increase in blood and plasma volume after the diuretic was injected. There was an initial fall in the circulating chloride followed by a secondary rise. There was relative sodium retention. There was an initial fall in the plasma albumin

15. Schmitz, H. L.: Studies on the Action of Diuretics: II. The Effect of Salyrgan on the Water Content of the Plasma as Measured by the Refractive Index, *J. Clin. Investigation* 12: 741-749 (Sept.) 1933.

followed by a secondary rise. There was a transitory reversal of the albumin-globulin ratio during the period of active diuresis, normal relationship becoming reestablished in twenty-four hours. In this case there was an immediate diuresis, reaching its peak during the second hour after the diuretic was injected.

Chart 5.—The effect of mercupurin on urinary output and body weight: In case 1 the drug was injected in three small doses each day. There was a well sustained diuresis and the weight loss followed a fairly straight line.

rationalize by clinical methods the complexities of a diuresis as acute as that produced by salyrgan. But at least they give evidence to show that in connection with the rapid excretion of large amounts of water and sodium chloride after salyrgan there may develop in the blood stream at the same time not only changes in the volume of the circulating blood which are significant but also significant changes in its chemical and physical composition.

Finally our observations bring to light certain practical implications regarding the best use of the mercurial diuretics. Throughout this study the circulation time by the decholin method, the vital capacity and the venous pressure was estimated at the time of each plasma volume determination. The results of these observations are of some interest.

The circulation time after salyrgan in most cases was slightly diminished twenty-four hours after the drug was injected but tended to be slightly prolonged when determined during the time of active diuresis. The vital capacity also tended to be slightly diminished when estimated during the time of active diuresis though increased at the end of the twenty-four hour period. The increases in vital capacity observed in our cases after salyrgan were not as pronounced as in the cases reported by Alsever and Levine;¹⁷ however, the general effect of salyrgan on this particular type of observation was the same in the two series.

The venous pressure in most instances tended to fall after diuresis was established, and usually twenty-four hours later to continue lower than before the diuretic was administered, an observation in agreement with

The behavior of the albumin and globulin in these three cases is worthy of comment, for it is contradictory to Schally's¹⁶ work. This investigator found an increase of the blood albumin after salyrgan injection, explaining his observations on the theory that in order for water to get from the tissue spaces into the capillary circulation albumin must be mobilized as well.

Our experiences, if they do nothing else, emphasize the difficulties entailed in any attempt to

Volini and Levitt's¹⁸ experience. There were exceptions, however, when the immediate effect of the diuretic appeared to be such as to cause temporarily a rise in venous pressure. There was one notable example of this reaction, patient N., on May 4, whose venous pressure rose from 135 mm. of water to 180 mm. a few hours after salyrgan was injected. And for a few bad minutes at the time, the patient was dyspneic and thoroughly uncomfortable. Our blood volume determination at this juncture was imperfect. We suspected, however, that the patient was one of those whose immediate response to salyrgan was an increased blood volume and that such an additional load was more than his circulation could manage comfortably.

Since from our experience it appears unpredictable what may be the immediate effect of a mercurial diuretic such as salyrgan on the blood volume and since striking changes in volume which are potentially harmful may occur quickly, it appears wise to continue with the use of such drugs conservatively and when they are first administered to continue the custom of testing each patient's individual susceptibility to them by the method of graded dosage.

It is possible that salyrgan or other mercurial diuretics may be administered more advantageously in small daily doses over a short period of time than by the single large dose method usually employed when the drug is given at three or four day intervals over a long period. The disadvantage with the traditional way of using a diuretic like salyrgan lies in the intermittence of the diuresis produced. A period of sharp diuresis is

Chart 6.—The effect of mercupurin on urinary output and body weight: In case 2 the drug was injected according to usual precedent in a single dose at three day intervals. The diuresis was intermittent and irregular, as was the loss in weight. The daily fluid intake was constant in both observations. The total amount of drug injected was the same in the two instances.

apt to be followed by a period of relative oliguria and redevelopment of edema. In theory the most effective results from these drugs would be obtained by so grading their dose and its timing that while the drug is in

16. Schally, A. O.: Veränderungen der Bluteiweisskörper bei der Salyrgandiurese, *Deutsches Arch. f. klin. Med.* 177: 368-376 (Dec.) 1934.

operation no noteworthy change in the plasma or blood volume develops and at the same time a continuous rather than intermittent diuresis is maintained.

With this idea in mind a few patients in congestive failure and with cardiac edema have been treated over a ten day period with three injections of mercupurin each day, each dose containing 0.5 cc. of the drug. Mercupurin instead of salyrgan was used as a mercurial entirely by chance. The results of these experiments are promising. A steady rather than intermittent diuresis developed and the patients' weight loss also followed a straight rather than a crooked line. The continued use of the diuretic in this manner did no harm: hematuria or other signs of renal irritation did not develop and the concentration of nonprotein nitrogen in the blood did not increase. Subjectively the patients felt notably improved.

CONCLUSION

Studies were undertaken to reinvestigate the effect of salyrgan on plasma and blood volume. The injection of salyrgan may be followed by significant changes in plasma and blood volume which seem inconsistent and which appear to follow no definite pattern. Possibly the sudden increase in blood volume which may occur following the injection of salyrgan is a handicap to a badly diseased heart. Methods of using the mercurial diuretics to avoid abrupt shifts in blood volume and to establish a continued moderate diuresis are possible and seem more logical than to administer such drugs so as to produce a transitory and even uncomfortable diuresis followed by a period of relative oliguria.

319 Longwood Avenue.

ABSTRACT OF DISCUSSION

DR. LEONARD G. ROWNTREE, Philadelphia: The experiments which have just been reported were broader and more comprehensive in scope than the experiments which Dr. George Brown and I carried on in this connection some fifteen years ago. Dr. Fitz was not satisfied with attempts at measuring plasma and blood volume; he took cognizance of the possibility of dilution phenomena; but even with this added bow to his string it was not possible to arrive at a definite conclusion as to a single mechanism. Apparently there is no one single pattern of change which accompanies the diuresis resulting from this drug. It seems to me that it is within the realm of possibility that the initial state of the blood and plasma may be at least one factor in determining what happens. Dr. Brown and I found, in experiments carried on at that time, that there were great differences in the blood and plasma as we encountered it in different types of edema. For instance, we had edema with low blood volume and low plasma volume and with normal values. We also saw edema with high plasma volume with dilution, and high plasma volume without dilution. These facts may be significant, but I do not believe that they constitute the controlling factor. As a result of all our studies we came to this conclusion, and I would like very much to get the thought of Dr. Swigert and Dr. Fitz on this matter. On the one side there is an edematous body, the kidney, and in between the plasma. One gives this drug and sees the effect, and one comes to the conclusion that the plasma might be just a passive agent and that the effects of the drug are primarily on the tissues or on the kidney, and hence whatever happened to them determined what was happening in the blood volume. The most important part of this contribution is the new method suggested for utilizing these mercurial compounds. I believe that the new method of getting results is infinitely better. It seems that Dr. Swigert and Dr. Fitz started out to do one thing but did not accomplish their purpose very successfully. However, during the process they did something which was more important than what they started out to do. They sought a scientific explanation of diuresis but devised a better method of

treatment, a method which should prove of great value to patients with edema. I should like to ask Dr. Fitz whether he thinks the role of plasma is active or passive. And has he seen any toxic effects from this newer method of employing the drug? Particularly has he seen collapse or hemorrhage attending its use?

DR. MAURICE BRUGER, New York: I should like to discuss the *modus operandi* of mercury diuresis. Although the markedly increased chloride excretion in the urine after the administration of mercury salts is generally appreciated, one frequently fails to realize how pronounced this may be at times. Some eleven years ago, I recall, Dr. Melville and I, while investigating antidotes for mercury bichloride poisoning, injected intravenously 1.2 mg. of mercury bichloride per kilogram into a dog with a bladder fistula. The increased chloride output in the urine was enormous. The control chloride output was 0.013 mg. per minute and within two hours this had increased to 22.4 mg. per minute, representing an increase of some 1,700 per cent. This speaks strongly for the extrarenal factor in mercury diuresis. It was Govaerts, I believe, who by kidney transplant experiments showed that a definite renal factor to account for mercury diuresis also exists. Drs. Swigert and Fitz noted that active salyrgan diuresis frequently placed an extra load on the already impaired heart. Was theophylline ever added to the salyrgan and if so was there any noticeable difference in cardiac efficiency during active diuresis?

DR. GEORGE R. HERRMANN, Galveston, Texas: Our experimental biologist, D. B. Calvin, has been working with this method of blood volume study for the past five years on problems of diuresis in animals. During the past year he has joined G. M. Decherd Jr. and me in a clinical restudy of diuresis mechanisms employing the plasma volume method of Gregerson, Gibson and Stead as modified by Gibson and Evans and by Gibson and Evelyn. In Calvin and Decherd's study in cases of edematous heart failure there weren't so many inconsistencies as Drs. Swigert and Fitz encountered. There were very definite and different trends of plasma shifts following salyrgan and aminophylline and a glucoside from *Digitalis lanata*. We have been interested for a long time in the different mechanisms of the various types of diuretics. In a large series of experiments, some fifteen, with the mercurial salyrgan, there was practically always an early and sustained concentration in the plasma volume that seemed to parallel diuresis. In only two cases were the results discordant. In one case no diuresis followed salyrgan and the plasma volume increased slightly. In the other case a delayed and temporary slight rise in plasma volume was recorded with a subsequent fall as soon as there was an augmentation of the urinary flow. Comparable studies with aminophylline revealed strikingly different plasma volume responses. Immediately after the intravenous aminophylline 0.5 Gm. there was a slight fall followed promptly and uniformly by a conspicuous rise in blood volume, increases considerably greater than those reported by Drs. Swigert and Fitz. This great increase in plasma volume following 0.5 Gm. (7½ grains) of aminophylline intravenously suggested divided dosage as a safety measure. During the time of the most profuse diuresis there was a characteristic tendency in the plasma volume to return toward the initial level. There was a shift in the plasma volume, apparently dependent, in part at least, on the balance established between the tissue fluid mobilization and the urinary output. The end result is usually plasma volume lower than that initially observed. With the glucoside, on the other hand, 2 mg. intravenously for patients with congestive failure, there was a shift in the plasma volume apparently according to the promptness and degree of the myocardial effect of the digitalis preparation. When there was immediate response the plasma volume decreased sharply as a satisfactory urinary output developed. When delayed, the plasma volume remained practically unchanged or increased slightly until diuresis was inaugurated, at which time it decreased.

DR. VERNE W. SWIGERT, Evanston, Ill.: The questions raised in discussion are still unsettled. Further work with regard to the mercurial diuretics and their behavior must be continued.

CHALK GOUT

A REPORT OF TWO CASES WITH A BRIEF SUMMARY OF SOME PREVIOUSLY REPORTED STUDIES ON CALCINOSIS

EDWARD F. ROSENBERG, M.D.

Fellow in Medicine, the Mayo Foundation
ROCHESTER, MINN.

The term "chalk gout" is occasionally used to designate a rare disease more generally known as "calcinosis circumscripta." In this condition calcium stones develop in the skin in the vicinity of peripheral joints.

Extensive reviews of the subject of calcinosis have been published during the past two decades: in Germany by Steinitz,¹ in America by Durham² and by Rothstein and Welt,³ in France by Weissenbach and his co-workers⁴ and in England by Atkinson and Weber⁵ and by Brooks.⁶ The first report of this disease in modern medical literature appeared in 1877 (Teissier⁷). However, Holländer⁸ has republished a curious record dated 1654 in which reference is made to a probable instance of this disease.

Steinitz distinguished two clinical types of calcinosis: (1) a circumscribed variety in which the calcium concretions are confined almost exclusively to the regions of the terminal phalanges of the fingers and toes and to the extensor portions of knees and elbows and (2) a diffuse or "universal" calcinosis in which the deposits are widely disseminated. In the diffuse type large portions of the skin may be converted into calcareous plates, or great fluctuant inflammatory masses may appear over which the skin may ulcerate and permit the discharge of gritty, chalk-like material. Interstitial tissues of muscles, tendons and nerve sheaths may be involved in the "universal" types. Internal viscera, however, are spared in both types of calcinosis. In practice, the distinguishing of two types has been applicable only to characteristic instances of the condition. Many individuals have been encountered in whom the pathologic picture was intermediate, fitting neither the circumscribed nor the diffuse type. The condition of these patients has been designated as "transitional." To the present, no constant metabolic or pathologic abnormalities have been found which distinguish either type of chalk gout. Conflicting reports on this phase of the problem have appeared, and the mechanism by

means of which calcium is deposited in both types is uncertain.

In 1938 Atkinson and Weber collected 137 cases of circumscribed calcinosis and seventy-eight of the universal type from the world literature. It appears that information concerning calcinosis must be sought in medical writings by searching under a great variety of names, among which are "tendino-fasciitis calcarea rheumatica," "tendinitis calcarea," "petrificato cutis," "calcinosis interstitialis" or "calcinosis universalis," "Raynaud's disease with calcareous degeneration" and "subcutaneous calcareous granulomata."

Chemically, the chalk stones have been found to consist mainly of calcium phosphate and calcium carbonate. These compounds are generally present in the same proportion as in bone. Small amounts of magnesium carbonate and phosphate, cholesterol and fatty acids have also been found in the deposits.

SPECIAL FEATURES OF CALCINOSIS CIRCUMSCRIPTA

The term "chalk gout" was suggested by Minkowski,⁹ and perhaps independently by Wichmann.⁹ Each, however, used the term "gout" in a different sense. To Minkowski the disease seemed to deserve designation as a form of gout because the deposits near joints of

Fig. 1 (case 1).—The fingers are diffusely enlarged and there is slight flexion contracture at the interphalangeal joints. Over the terminal joints are elevations caused by the underlying chalk stones. The skin over the fingers is tense, firm and shiny and shows scars resulting from the ulceration of previous deposits of calcium.

stonelike calcium concretions resembled the tophaceous deposits of true uratic gout. Wichmann used the term "gout" because he believed that the disease resulted from a special metabolic fault—calcium diathesis analogous to uratic diathesis. Wichmann's contention is not yet proved.

CLINICAL FEATURES OF CALCINOSIS CIRCUMSCRIPTA

Usually this disease runs a mild course. It appears most frequently in elderly persons and somewhat more often in women than in men (in fifty-seven of seventy-one cases collected by Steinitz the patients were females). The disease develops insidiously. Stiffness and aching of joints appear in the affected regions, and the subcutaneous deposits of calcium develop slowly. Calcified regions may or may not be painful. The physician may encounter the deposits by chance in the study of roentgenograms. According to Steinitz, scleroderma or sclerodactylia accompanies calcinosis circumscripta in more than 40 per cent of cases and, as is true in uncomplicated scleroderma, vasospastic phenomena involving the digits occur commonly. These vasospastic symptoms may take the form of characteristic attacks

similar to those of Raynaud's disease, with the usual series of changes in color involving the acral regions. Some patients complain only of blueness or coldness of the extremities. Ulceration of the skin may occur over the nodules, even in the circumscribed type of the disease, and extrusion of the calcareous material may result.

The Joints.—Descriptions of the status of the joints in patients suffering from calcinosis circumscripta have been very meager in most reports dealing with this disease, although it has been stated commonly that the affected individuals complain of pains in the joints. Costello's¹⁰ patient had "generalized arthritic pains with swelling and thickening of the fingers and toes." Atkinson and Weber stated that the joints are unaffected, meaning that intra-articular disease does not occur. Rothstein and Welt, in their review of calcinosis in children, stated that in one of twenty cases the joints were fixed and motion was limited by the development of contractures. Calcific deposits were found within the joints in two cases. "Chronic arthritis deformans" caused an irregularity and deformity in the articulating surfaces in one case reviewed by these authors. Thus

by the administration of irradiated substances and extracts of parathyroid tissue have not reproduced a syndrome like calcinosis and (4) metabolic studies of calcium in patients who have calcinosis have often yielded normal results, and when abnormal effects have been noted there has been no general agreement concerning, or satisfactory confirmation of, the effects from independent laboratories. Those who favor the hypothesis that local destructive tissue change precedes calcification point to the frequency with which the disease is associated with scleroderma. In scleroderma hyaline changes occur in the subcutaneous tissues. However, in some 60 per cent of cases in Steinitz's series the patients did not have associated scleroderma, and recent histologic studies by Bauer, Marble and Bennett¹¹ have not confirmed the presence of preexisting necrosis of tissue in regions in which calcium has been deposited. The search for an explanation must continue.

REPORT OF CASES

CASE 1.—A woman aged 51 came to the Mayo Clinic complaining of pain and stiffness of the joints. Her medical history was irrelevant excepting that she had never menstruated and had experienced no pregnancies.

Fig. 2 (case 1).—Deposits of chalk-like material are visible about the phalanges of the fingers and toes. Several terminal interphalangeal joints in the hands have been markedly destroyed by an arthritic process, and similar hypertrophic changes are seen about the midinterphalangeal joints: a, anteroposterior view of right hand; b, lateral view; c, view of feet to show toes.

it would appear that the disease is but rarely associated with the syndrome of progressive chronic atrophic arthritis.

PATHOGENESIS

The mechanism by means of which deposition of calcium develops is unknown. The numerous hypotheses which have been advanced may be divided into two types. The first considers the disease to be a metabolic disorder analogous to uratic gout; the disease is thought to be based on an alteration in calcium chemistry. The second hypothesis holds that the deposition of calcium results after local changes have taken place in connective tissue of such a nature that an increase in affinity for calcium salts exists in the damaged portions. Exponents of both arguments have been unsuccessful thus far in accumulating conclusive evidence. Against the "humoral" theory are the facts that (1) the bony skeleton is usually intact, (2) determinations of the values of various organic and inorganic constituents of the blood have, for the most part, given normal results, (3) experiments in which hypercalcemia was secured

Four years before her visit to the clinic she had noted the gradual onset of dull aching pain in the tips of the toes. Within a few months walking became difficult because of her painful feet. Her knees also became painful. A year after the onset of the disease, the finger tips became painful, especially on attempts to grip, as in turning a doorknob. Within another year, aching and stiffness had extended to elbows and shoulders. The stiffness was particularly marked after inactivity. The patient often attracted considerable attention when she was leaving a theater, because of stiffness and difficulty in straightening to the erect position.

For two years she had noted attacks of pain in the finger tips associated with changes in color from white to bluish red. These occurred when she was exposed to cold. She had obtained relief from these attacks by immersing the hands in warm water.

Results of the physical examination were essentially negative excepting for the extremities. There was limitation of ability to abduct the right shoulder graded 2 (on the basis of 1 to 4). The forearms could be extended only to 175 degrees because of slight contractures in flexion at the elbow joints. There was limitation of motion at the joints of the fingers so that she was unable to close the fists tightly. The fingers were diffusely

thickened, but no spindle-like enlargement of knuckles was noted. The regions of the terminal phalanges of all the fingers were tender to pressure and the overlying skin was indurated, dry and scaly. On the dorsal aspect of several fingers small subcutaneous nodules could be seen and felt; they were from 2 to 3 mm. in diameter. The skin over some of these nodules appeared to be scarred (fig. 1). In these regions ulceration, discharge of nodules and subsequent healing had occurred. Eight or ten similar nodules could be seen shining through the skin of the lateral aspect of the left elbow, and similar small deposits were present about the anterior aspects of the knees. Both ankles were swollen graded 1+ but were not tender, and the sub-astragaloid regions were markedly limited in range of motion.

Blood counts and examinations of the urine gave essentially negative results. The value for blood calcium was 9.6 mg. per hundred cubic centimeters and for phosphorus 3.4 mg. per hundred cubic centimeters. The value for serum phosphatase was 1.7 units. Roentgenograms of the right hand (fig. 2 a and b) showed extensive destructive changes caused by arthritis, involving the terminal and middle phalangeal joints with heavy deposits of calcium in the subcutaneous tissues of the terminal phalangeal portions and destruction of the adjacent bone of the terminal phalanx. In the roentgenograms of the feet (fig. 2 c) there was

feet, knees and elbows, with dryness and cracking of the skin of the hands. He had been very active in athletics, having participated in football, baseball, track and basketball, thus having been exposed to numerous traumas for many years. The history of the present illness was as follows: Shortly after his enlistment in the army in 1918 he had noticed a stiffness of the hands, with soreness of the joints and a dryness and cracking of the skin of the fingers. To close the hands was painful. He could not play baseball because it caused pain in the hands. Two or three months later he had noticed soreness and stiffness of the joints of the feet and knees. His joints limbered up with exercise. A year which he spent in New Mexico for a change in climate did not help. Alveolectomy and tonsillectomy had been done with no improvement.

During the year before the patient's visit to the clinic, small lumps had appeared in the ends of the fingers, and he said that the tips of the fingers had seemed to feel sore.

He had noted some difficulty in regulation of the temperature in the feet and hands; at times the feet were very cold and could be warmed only with great difficulty, and at times he awakened in the morning with very warm hands, which assumed a normal temperature only after exercise. His hands easily turned blue with chilling.

Fig. 3 (case 2).—The skin over the terminal portions of the fingers is cracked, and numerous scars are visible over the region of the terminal interphalangeal joints, where ulceration and discharge of chalk deposits have taken place.

noted marked periostitis of the shafts of the second, third and fourth metatarsal bones bilaterally and evidence of inflammatory and destructive changes in joints involving the tarsal joints. Deposits of calcium were seen about the phalanges of the toes similar to the deposits noted in the hands. A curious portion of subperiosteal rarefaction was noted in the roentgenogram of the left elbow at the site of the two regions of subcutaneous deposition of calcium along the outer aspect of the humerus. Portions of subcutaneous calcification were also noted about the lower aspect of the right knee.

Examination of the capillaries of the nail folds was carried out according to the technic of Lombard.¹² They were very difficult to see because of the deformities of the fingers. However, it was noted that the number of loops was decreased in each field. The individual loops were large, were irregular in shape, and appeared to have marked loss of tone, resembling the capillaries frequently observed in the presence of scleroderma. No results of treatment can be reported at this time.

CASE 2.—A man aged 45 when he came to the Mayo Clinic in 1928 complained chiefly of stiffness and soreness of the hands,

On physical examination the patient was found to be well developed and well nourished. The skin covering the hands was very dry; this was most marked over the dorsal portions of the fingers and especially over the terminal phalangeal joints (fig. 3), where the skin was hard, fissured, shiny and red. The same appearance was noted in the skin overlying the proximal portions of the fingers. The skin over the metacarpophalangeal joints also was dry, shiny and tight. On the end of the thumb and index finger of the right hand and of the thumb, index finger and fourth digit of the left hand, small hard nodules could be felt under the skin. The patient was unable to close his hands completely. The skin over the elbows was dry and somewhat scaly. The skin over the toes was shiny and red but the changes in the skin in this region were less marked than those in the fingers. The skin over the knees was somewhat tight and shiny. Multiple ricelike bodies were noted in the scalp along the upper border of the forehead.

The appearance of the skin was not exactly that presented by scleroderma or Raynaud's disease, although these conditions were simulated by some features of the patient's condition. The cyanosis of the fingers, the trophic changes that have occurred in the skin and the deposits of calcium suggested a vascular disease of the skin.

12. Lombard, W. P.: The Blood Pressure in the Arterioles, Capillaries and Small Veins of the Human Skin, *Am. J. Physiol.* 29: 335-362 (Jan.) 1912.

Routine examination of the urine and the blood counts yielded essentially negative results. The value for serum calcium was 10.2 mg. on one occasion and 9.3 mg. on another determination. Diffusible calcium was 5.0 mg. and nondiffusible calcium was 4.3 mg. The concentration of uric acid in the blood was 3.6 mg. per hundred cubic centimeters.

Roentgenograms of the hands showed slight evidence of hypertrophic arthritis involving the terminal phalangeal joints. Heavy deposits of calcium were seen about the terminal phalanges of the first, second and fourth digits of both hands. The bones did not appear to be diseased on the left side. In the right hand (fig. 4), however, the calcium appeared to have been deposited near regions wherein the bone of the phalanx had been eroded.

PROGNOSIS

Very little information is available regarding the ultimate fate of persons who have this disease. Death has been reported as having been caused by "circulatory weakness," cancer of the stomach, pulmonary tuberculosis, uremia, and asphyxia resulting from obstruction by a bolus of food. Thus the disease in itself is not fatal but death results from intercurrent illness.

Fig. 4 (case 2).—a, anteroposterior view of right hand; b, lateral view. Heavy deposits of chalk may be seen about the terminal phalangeal regions. The bone has apparently been eroded adjoining some of the deposits. Hypertrophic arthritis (possibly unrelated) may be noted in the terminal interphalangeal joint of the right fifth finger.

TREATMENT

Many treatments have been tried for patients suffering from this disease. Some reputedly have been successful. Surgeons have operated to remove the autonomic nerve supply to blood vessels, to remove the thyroid gland, the parathyroid glands and often to excise the nodules of chalk. Extracts containing the hormones of the pancreas, pituitary body, ovary, parathyroid glands and thyroid glands have been administered. Iodides, phosphates, acetylcholine and other drugs have been tried. Heliotherapy, roentgen therapy, electrophoresis and a lemon diet have been recommended. More recent reports have dealt with interesting attempts to treat this disease by applying newer methods of mobilizing calcium. Craig and Lyall¹³ administered disodium hydrogen phosphate in the attempt to cause interference with the normal absorption of calcium, the expectation being that the bones subsequently would draw on calcium from the deposits of chalk. Kennedy¹⁴ has had success with the use of a ketogenic diet. Ammonium chloride, sodium citrate and parathyroid extract have been used. Some patients have recovered without treatment.

Clinical Notes, Suggestions and New Instruments

A CASE OF TRICHINOSIS PRESENTING CHEMOSIS OF THE BULBAR CONJUNCTIVA

LOUIS LEHRFELD, M.D., AND CARL F. BREISACHER, M.D.
PHILADELPHIA

Bulbar chemosis, alone or with other symptoms, is not generally considered to be a symptom of trichinosis. Osler¹ considers edema of the eyelids a characteristic symptom but does not call attention to bulbar chemosis in this disease. Foster Moore² makes no mention of it, and it is not described in standard ophthalmologic textbooks.³ There are, however, several references to this symptom in the ophthalmic literature and also in the general medical journals. Parker⁴ in 1907 reported six cases, four of which presented lid and conjunctival edema as the chief complaint. Carter⁵ in 1930 reported three cases and called particular attention to bulbar chemosis as a prominent symptom. Stoll⁶ in 1929 presented two cases in both of which chemosis was the chief complaint. Hickling,⁷ Thomas and Cooper⁸ and Key⁹ have also made mention of this symptom.

REPORT OF CASE

C. F., a white female, first came to the emergency room of the Wills Hospital on April 29, 1940, complaining of swelling of the eyes. She gave a rather indefinite history of slight puffiness of the lids of both eyes with swelling of the "whites of the eyes" beginning about one week prior to admission. The swelling of the lid became less but the swelling of the "white portion" increased, with tearing. A feeling of feverishness and malaise accompanied the ocular symptoms.

On examination, the eyelids of both eyes presented slight swelling, both upper and lower. There was no edema of the face or forehead. The conjunctiva of each eye, particularly the lower bulbar conjunctiva, was intensely chemotic, so marked that it protruded between the lids, preventing complete closure of the latter. The conjunctival vessels were slightly injected and the entire conjunctiva had a yellowish, waxy appearance. Both corners were clear, the irises were normal and the pupils reacted normally. The fundus was normal and healthy bilaterally.

The disease trichinosis was suspected and the patient was referred for a complete blood count the following day. This showed a white cell count of 10,800, of which 53 per cent were neutrophils, 25 per cent eosinophils, 17 per cent small lymphocytes and 5 per cent monocytes. Because of the eosinophilia, the patient was admitted to the Wills Hospital the same day, April 30, for further study.

On admission, the temperature was normal, rose to 99.8 F. the third day, May 2, and continued irregularly thereafter, rising to 105 F. on May 6, thereafter gradually falling. After May 9, until discharge May 17, the fever never rose to above 100 F. and was intermittent. The respiratory rate varied from 18 to 28 a minute, the pulse rate from 88 to 112.

Results of the blood counts are given in the accompanying table.

Laboratory examinations were made; the urine was normal and the Wassermann reaction negative. Dental and rhinologic consultants returned negative reports. The stool was examined but no parasites or ova were found. On May 6 (seven days after admission) a small section of the gastrocnemius muscle was excised, sectioned, stained and examined by Dr. J. H. Clark (Philadelphia General Hospital), who found the encysted larvae of *Trichinella spiralis*.

Dr. C. C. A. Banes, who made a general physical examination, found no signs except the ocular ones already mentioned but concurred in the diagnosis.

Further questioning of the patient produced a dubious history of ingestion of uncooked pork two days before the first symptoms were noted. This was not considered to be the offending material, since the time elapsing between ingestion and the appearance of symptoms was very short.

The clinical course of the disease was extremely mild during hospitalization, there being only mild general malaise in spite of the high fever. The chemosis had disappeared by May 6 (the seventh day after admission), leaving only a slight bulbar injection. No swelling of any other part was noted until three days prior to discharge, when the left ankle was noted to be slightly puffy. This had abated on dismissal from the hospital, May 17.

The only treatment consisted in purging with magnesium sulfate every third day (there was no diarrhea at any time), complete rest in bed and a boric acid flush to the eyes several times daily.

In spite of advice to the contrary, the patient signed her release on May 17 (eighteen days after admission) and when last seen on May 28 was symptom free and apparently in excellent health.

After the patient had been discharged, the sections of gastrocnemius muscle were submitted to Dr. John Bozicevich of the United States Public Health Service for examination.¹⁰ In his opinion the well developed cysts enclosing third stage larvae of *Trichinella spiralis* were indicative of an old infestation, but it was considered that, from the clinical features of the case, there had been a recent superimposed infestation.

Results of Blood Counts

Date	Hemo- globin	Red Blood Cells	White Blood Cells	Neu- tro- phils	Eosino- phils	Baso- phils	Lym- pho- cytes	Mono- cytes

COMMENT

No specific treatment for trichinosis is available. In recent years the use of neosarsphenamine intravenously has been advocated but with varying and questionable results. It was not considered advisable in this case, since it was not one of severe involvement.

The peculiar waxy or yellow jelly-like appearance of the bulbar conjunctiva seen in this case was also observed by Carter.⁵ Herrenschwand¹¹ in 1927 was privileged to study an eye involved by trichinae at autopsy. According to his observations the bulbar conjunctiva showed marked round cell infiltration with a superabundance of goblet cells. Trichinae were present in the ocular muscles, mainly in the belly of the muscle and not near the tendinous attachment. They were present in greater numbers than in the skeletal muscles.

It has been considered that edema of the conjunctiva and lids is concomitant with infestation of the rectus muscles with the trichinae. Verhoeff¹² questions this, however, maintaining that chemosis appears before general muscular symptoms develop.

In most of the cases reported, pain on movement of the eyes was present; but the case here reported did not show this

feature. Also in other cases the edema was more prominent over the insertions of internal and external rectus muscles with small punctate hemorrhages, but this too was absent in our case.

The fact that chemosis is a frequent and prominent symptom of the disease trichinosis has not been adequately stressed. As mentioned previously, Carter⁵ drew attention to this and went so far as to conjecture its presence in 50 per cent of cases. If this is so, it is apparent that many cases are missed by the ophthalmologist. In recent years many writers have reported encysted larvae of *Trichinella spiralis* in muscles of a relatively large percentage of autopsies. In these cases no history of infestation was secured. Perhaps the ophthalmologist can in the future detect more of these cases. The importance of a blood count in any case of conjunctival edema presenting a waxy yellow appearance, and without apparent cause, cannot be overemphasized. Certainly the disease should be kept in mind and not considered remote from the practice of ophthalmology.

Sixteenth and Spring Garden streets.

Special Clinical Article

RECENT DEVELOPMENTS IN THE SUR- GICAL MANAGEMENT OF THE OBSTRUCTING PROSTATE

CLINICAL LECTURE AT NEW YORK SESSION

JOSEPH FRANCIS McCARTHY, M.D.

NEW YORK

The extraordinary advance of medicine in the surgical specialties is nowhere better illustrated than in the field of prostatic surgery. The past ten years has seen unfolded revolutionary instrumental methods of correction of obstructing prostatism. Naturally this departure from formerly accepted principles has occasioned much discussion, some of which has been constructive. That it has, however, successfully withstood the acid test of time is indicated by the general acceptance on the part of the profession of the method as such after a ten year period of trial and error. Another constructive effect of the many communications on the subject, with their attendant discussions, has been to occasion a reevaluation of the formerly accepted methods of open surgical approach. This state of mind has been and will continue to be the occasion of further progress in technic as well as in other factors. I am well aware of the advanced position assumed by some of my colleagues that instrumental operations have practically replaced open surgery. Since, however, I regard this as a period of evolution, a word of caution is offered against the general acceptance of this point of view.

Psychologic limitations have never been so apparent as in the writings of some of the commentators on the surgery of the prostate gland. Their theses have been in large measure a reflection of personal predilections, aptitude, precepts of their predecessors or environmental influences. If these premises are even in part acceptable, it logically follows that one who presumes to speak or write with even measurable authority should, however he concludes it, begin at least his dissertation in an atmosphere of detachment. The other thought that at once arises which is somewhat removed from the particular subject and perhaps

Read in the General Scientific Meetings at the Ninety-First Annual Session of the American Medical Association, New York, June 10, 1940. J. S. Ritter, S. E. Kramer, Charles Lippow and P. A. Narath gave valuable assistance and criticism in the preparation of this communication.

a bit academic but which "sticks out like a sore thumb" is the altogether obvious limitations, professionally speaking, of the young medical man who begins and concludes his institutional medical education under the egis of one educational center.

The romance of the prostate, surgically speaking, is the story of continued progress in technical procedure, improved methods, lowered mortality, briefer hospital domicile, lessened morbidity. When it is realized that these advances vitally affect 25 per cent of male mankind, in other words one fourth of the matured minds and bodies of the male portion of the nation, all concerned in this tremendously constructive piece of sociological endeavor merit the comforting feeling of a job well done. Far from considering the job as finished, however, this situation should be regarded as merely a point of departure to other and greater advances. The complacent will, as always, "miss the boat." With this prelude, let us consider the probable routes of further progression.

One of the great forward steps in suprapubic prostatectomy was the inauguration by Lilienthal of the two step operation. This was a veritable life saving innovation. But "time marches on" and the question arises whether, with the marked progress in technical equipment, there may not be a general reversion to the one step operation. There are two well grounded reasons for interposing this question. First, we have ample clinical experience to justify the belief that the vertical incision for cystotomy, so commonly employed in this country, should, save in exceptional instances, be abandoned. It has nothing to commend it except precedent. It has played a not unimportant role in the high mortality of the past. For the benefit of those who may not have read my prior description, the approach is herewith appended:

A transverse incision 5 cm. in length, 5 cm. above the middle of the symphysis includes the superficial tissues and the muscle sheath. One then separates the muscle longitudinally and the parts are retracted. Prior to incision, the bladder has been filled to two thirds capacity and a catheter is left remaining with loaded syringe attached. At this point the bladder is palpated so that one senses the further expanding organ as the additional fluid is introduced. The operator with sharp dissection then exposes the bladder wall, which is seized with Allis clamps above and below the point where the transverse cut is to be made. It should be emphasized that a transverse incision in the bladder is at once more satisfactory from the standpoint of approach and heals much more kindly than does the vertical. The major steps from this point on apply to either one or two stage removal of the gland. In the two stage, a suitable tube is then introduced through the opening. I employ a fair size mushroom catheter, preferably the angulated type. Then a circular suture is taken and closed snugly about the tube as the mushroom part is brought up against the bladder wall. The sutures are not cut, as they are intended later to be used for traction on the bladder to obliterate spaces for possible infection. The ends of the suture about the tube are then passed through the incised rectus sheath, one above and one below the transverse incision, and when drawn on later and tied, brings the bladder wall close to the abdominal wall. A small piece of rubber dam is introduced and the incision in the sheath closed by No. 3 or 4 chromic gut sutures. Final closure may be made by two or three figure of eight tension sutures.

TREATMENT OF PROSTATIC BED AFTER ENUCLEATION

There has been a gradual change in treatment of this bleeding surface. For many years we remained, as Robert T. Morris facetiously described it, in the era of taxidermy—we stuffed our patients with gauze. Then came the compression bags of Hagner, Pilcher and others; next suture of the cut edges. Later, Harris effected in most of his cases almost complete hemostasis by deep suture. For one or a number of reasons, none of these methods of arrestation have proved so generally acceptable as to rule out the others. It is my hope that the method to be described may prove acceptable, after sufficient trial by others suitably equipped. After suprapubic enucleation of the gland, the cavity is somewhat firmly packed with a long 2 inch gauze roll taken from water at a temperature just about as high as the fingers of the operator can support. Bimanual compression supplements this for a few minutes and the gauze is then removed. Prior to enucleation the patient has been prepared as for a cystoscopy. The visualized electrotome is now introduced through the urethra; suction is begun at the site of the incision as the flow of water through the endoscope is started. One is surprised at the clarity of vision and the precision with which bleeding points can be seen and coagulated with the gap current. Where satisfactory hemostasis is accomplished, the use of packing or the compression bag is unnecessary. When it fails nothing is lost, as the other measures are still available. Finally, it obviates extensive tissue separation should one desire to suture or clamp from above. If the endoscopic method of arrestation of bleeding with the visualized electrotome as here described proves effective on further trial by others as well as by myself, it may obviate the blind and, it may be said, unsurgical method of packing or bag compression in general use today.

My objective in this tentative proposal is to obtain an early decision from a group of qualified workers in this field. Should time and usage prove these technical steps acceptable, it will perhaps be conceded that the important factors which militated against the one stage suprapubic prostatectomy may thus be eliminated. These factors may be summarized as follows: prevesical or perivesical infection; secondary bleeding shortly postoperative, or later bleeding incidental to removal of compression apparatus; discomfort of the patient.

For purpose of clarification my point of view is that infection has been reduced to a minimum by the transverse approach as previously described, the constitutional reaction strikingly lessened and healing hastened. Here the clinical background in the method is sufficient to warrant the assumption that with certain selective exceptions the now generally used vertical incision for suprapubic approach will be abandoned and a reconsideration of the necessity for the two stage operation would appear to be in order.

PERINEAL APPROACH

I have never been completely convinced that most of the technical methods of perineal prostatectomy found in textbooks and monographs have been based on sound anatomic or physiologic principles. With this general assumption, it is in order to particularize. First, the practice of many years of an incision over each of the prominent lateral lobes and the piecemeal removal of such lobes is certainly an error. It is merely a replica of the method of Freyer in suprapubic removal, a method long since abandoned for good and proper reasons. Intra-urethral enucleation is the one rational

method of surgical removal of the prostate, either from above or from below. Thus one conserves the internal sphincter. This may be easily proved by subsequent cystographic study. Then too the impression of the technical difficulties of the operation have been overstressed. The following technic offers a rational and easy method:

The first arm of the incision is transverse, and each terminal of this incision is extended by an additional one downward and outward to the tuberosity of the ischium. These incisions are deepened and the ischio-rectal fossa on each side sufficiently dilated to outline the central tendon. The finger of the left hand is then introduced into the rectum and, with appropriate retraction, the last mentioned structure and the rectourethralis muscle are cut sharply and separated bluntly until the bifurcation of the levator ani muscles is reached. A bougie or a Foley catheter bag on which traction may be exerted, which has previously been passed through the urethra, is now palpated as a guide to its position. From the perineum to this point the anterior wall of the rectum takes a direction upward toward the urethra. It is essential therefore for the occasional operator, and wise for the expert, to give himself the benefit of the palpating finger in the rectum up to this point in the operation. From here on, however, one has to deal in large measure with areolar connective tissue and with a descending anterior rectal wall, which can be separated by blunt dissection up to the fascia of Denonvilliers. Consequently the palpating finger is now withdrawn, new gloves are applied and the dissection is proceeded with as in any surgically clean operation. When the fascia covering the prostate has been incised, also transversely, the prostate is exposed and a transverse incision is made into the prostatic urethra posterior to the verumontanum. The Foley bag is now removed, a firm rubber bag retractor is introduced into the bladder (Parker Sym's type), the prostate brought into the field and the gland removed (intra-urethrally) usually in one piece. From this point on, whatever procedure one elects may be carried out. Only essential details are herein described.

COMMENTARY

I believe (a recently acquired view) that elaborate dissection of the ischio-rectal fossae is unnecessary, that when carried out it prolongs wound healing and adds to the danger of infection. The model of bladder retractor here submitted and which has rested in the archives for many years is a frank copy of the Parker Sym's retractor. In the opinion of those of us who have seen it in operation it is completely satisfactory. As a matter of fact, Parker Sym's, with his three minute prostatectomy of fifteen or twenty years back, had at least some of the essentials of a perfect perineal prostatectomy. He made the usual vertical incision in the perineum such as was used for an external urethrotomy, cut down on a staff in the urethra, introduced his bag and, under traction, enucleated the prostate. The cardinal failure here was his complete indifference to the external sphincter.

The approach described obviates the defects just reviewed. Moreover, in a perineal prostatectomy based on sound anatomic and physiologic consideration there should be no excuse for damage to either sphincters or rectum. The foregoing details on technic are submitted merely as an expression of my present opinion as to the probable lines along which further progress may be achieved. They are presented also as an indi-

cation that I am convinced we are still in a period of evolution; that, unless and until one or another method has definitely established its superiority in average hands, other methods of proved value should not be altogether abandoned. They must be subjected, however, to sustained and critical scrutiny, as the present accepted methods are by no means perfect. Obviously, complacent acceptance has no place in investigative endeavors.

ENDOSCOPIC PROSTATIC RESECTION

The innovation of recent years of endoscopic prostatic resection has successfully withstood an unprecedented avalanche of dogmatic assertion, contentious debate and premature conclusions. Many of the early accidents, the mortalities inherent in a highly technical method, could have been avoided by a more conservative, a more deliberate, approach, a better apprenticeship. The literature is replete with proof of this statement. The late statistics of those with large clinical background reveal gratifying figures on functional result, mortality, morbidity and hospital domicile. In increasing measure throughout the world, the method that I have advocated, with concurrent improvements, is gradually replacing open operations. In some responsible clinics it has practically replaced open surgery. In our clinic, during the early stages of enthusiasm, open surgery was reduced to a minimum; then came a period of resumption of older methods in a moderate percentage. The third era, the present, finds us performing endoscopic resection in an ever growing percentage of our cases.

The technic remains about the same as described in previous communications. Of course, since the advent of the sulfanilamides, we have lost our fear of infection. Operative time is greatly shortened, as the removal of the tissue is done without interruption, to remove the pieces. These are later evacuated by means of an aspiration syringe designed for the purpose. Then too, with more efficient appliances for the after-care and improved cutting and coagulating apparatus, postoperative complications are rare indeed. The one complication that has harassed the method is its appeal to the inexperienced or the audacious. The thing appears simple when performed by the experienced. What the observer fails to note is the necessity for much prior apprenticeship with the panendoscope and an exact knowledge of conformation of these structures in the normal, without which the extent of pathologic departures and factors of safety cannot be correctly interpreted. Adequate and especially trained personnel for postoperative care are equally necessary.

COLLATERAL TOPICS

Transfusion.—This subject is introduced here merely to give expression to a personal point of view. The clotting time, hemoglobin and red cell count, blood grouping and so on should of course be matters of routine, as preoperative preparedness is an important part of the postoperative management. It may be added that a red cell and hemoglobin estimation immediately following operation is also of value. When and if a transfusion is indicated, I believe that fractional transfusion of citrated blood serves the purpose quite as satisfactorily as direct transfusion of whole blood; moreover, it obviates some of the disadvantages of the latter. There is an absence of the psychic manifestations attendant on direct transfusion. It should always be remembered that we frequently are dealing with the arteriosclerotic, the myocarditic type of patient. That when direct transfusion is employed there is a natural

tendency to give larger amounts than with the citrate method, in which small amounts can be administered in the patient's room repeatedly when necessary and the febrile reaction is not so pronounced. It is now some years since I have employed direct transfusion.

Pharmacology.—A very interesting experience was noted with sulfapyridine, in a resection case in which there occurred a secondary bleeding of sufficient importance to send the patient to the cystoscopic room for aspiration of clots and endoscopic coagulation of bleeding points. A hemoglobin and red cell estimation was made at this time, 4,800,000 red cells and 90 per cent hemoglobin. On the same evening one of the interns thought the patient was developing a bronchopneumonia and administered sulfapyridine. Forty-eight hours later, without any additional bleeding, the hemoglobin was 48 per cent, red cells 2,400,000. The drug was immediately discontinued, yet the further drop in hemoglobin and red cell count became so marked as to necessitate fractional transfusion. Caution, therefore, and repeated blood study should be the watchwords with this group. I have, with few exceptions, restricted my patients to small doses of drugs of the sulfonamide group as urinary antiseptics, from 20 to 30 grains (1.3 to 2 Gm.) daily. Generally satisfactory, occasionally it does not work out, when resort is had to more specific study and other methods. Ritter reports a case of bilateral kidney abscess, in one of the public hospitals, wherein the temperature remained low for most of the two months period of intermittent administration of one of the drugs of the group mentioned. At autopsy there were found discrete abscesses of the kidneys together with crystals of the drug in the kidney tissue.

There is also too much empiricism manifested in the matter of administration of proprietary hypnotics, too little scrutiny of or inquiry into the question of possible idiosyncrasies, too little reliance on the pharmacopeia and too much on the drug house man. Paraldehyde in oil, for example, administered by rectal tube in divided doses, while not to be recommended for kissing the baby after administration, is one of the safest and best of all drugs for sedation or as an aid in block anesthesia.

Anesthesia.—Inhalation or general anesthesia is very rarely employed in our work. For brief cystoscopic operative manipulations, intravenous anesthesia is occasionally used. It must be remembered that the margin of safety here is low. One in 100 administrations of a drug customarily employed was followed by a temporary state of coma and the patient was aroused only to fall again into a comatose condition which lasted through three, for us, very anxious days. Fortunately, the condition cleared up without further untoward end result. Inhalation anesthesia in the ordinary urologic operations is merely a labor saving device for the over busy or impatient individual.

Spinal Anesthesia.—This of course is largely a one man job. When it is administered by a variety of interns, things are apt to happen from time to time. For the average prostatic resection or a not too prolonged bladder operation, 50 mg. of one or another of the procaine hydrochloride group will prove both safe and satisfactory when not contraindicated. My technic is to diffuse the drug with the spinal fluid. It has however been noted that when the spinal fluid seems to be under pressure the anesthetic effect is not as prolonged from this amount of drug as under normal conditions. Immediately after the spinal is administered, an intravenous salt solution is begun and the

rate of flow regulated in accordance with the blood pressure readings from the other arm. I am disposed to refrain from the use of morphine or its derivatives in conjunction with the barbiturate group as supplemental to spinal anesthesia because of its depressing effect on the vital centers and the possibility of respiratory failure.

Local Anesthesia.—This is considered here only in conjunction with prostatic resection. Others have reported cases conducted under this type of anesthesia,¹ but its potentiality for good has been ignored. There undoubtedly exists a considerable group of debilitated old men, another small group with antecedent history of anginal attacks, and others wherein one is loath to or refuses to administer inhalation or spinal anesthesia. In many such cases, in my opinion, resection may be successfully done in one or more stages under local anesthesia. It may very well be the practice of the future that the earliest manifestations of prostatic obstruction will be subjected to this simple and safe procedure.

The technic that I employ is as follows: Paraldehyde in oil is administered by rectum in divided doses, beginning some hours prior to operation. With the patient on the operating table a long needle is introduced into the perineum and with the guiding finger in the rectum the needle is passed directly into the prostate in the midline and a 1 per cent solution of procaine hydrochloride is injected. The lateral lobes are then similarly injected. Twenty minutes prior to this step a topical anesthetic solution has been injected into the bladder and urethra. When sufficient time has elapsed, the visualized electrotome is introduced. This instrument is now provided with a new attachment—a long needle with a rack and pinion adjustment affording a back and forth movement. The needle is now introduced into the urethra, first in the midline, and the solution injected under the sphincter as far as the mucosa on its postsphincteric aspect and then well into the lateral lobes on each side. The manipulation is so precise that one can at will and under perfect vision infiltrate any part of the prostatic urethra. While it is to be admitted that I am only in the ground breaking phase of this type of anesthesia in prostatic resection, my experience with it encourages in me the belief in its availability in the type of cases mentioned. I cannot escape the feeling that improper selection of anesthesia in operations on debilitated old men is the major factor in mortality.

Calculous Prostate.—This condition occurs with sufficient frequency to warrant the practice of routine x-ray study. It may also simulate malignancy to the palpating finger. Because of the fact that the ordinary suprapubic or perineal prostatectomy is unsatisfactory in this disease there remain but two methods of attack—total excision of the gland by way of the perineum or endoscopic resection. For a long time I have remained skeptical of the effectiveness of the latter method. Recent experience, however, has been so gratifying that it is my belief the method justifies itself and may enjoy a larger role.

Resection and Malignancy.—Attention has been drawn to the fact that a certain proportion of obstructing prostates, let us say 15 per cent, are actually or potentially malignant. It has also been argued that if such is the case why not employ prostatectomy in all

1. Wishard, W. N., Jr.; Hamer, H. G., and Mertz, H. O.: Local Infiltration Anesthesia of the Prostate Preliminary to Resection, J. A. M. A. 102: 32-35 (Jan. 6) 1934.

such cases by open surgery? This certainly merits full and frank discussion. The first thought that comes to mind is, What has become of the malignant cases in the clinics, wherein the claim is made that only in a considerably smaller percentage of cases has there been any occasion for open surgery? My departmental associates S. E. Kramer and J. S. Ritter have given utterance to some interesting opinions on this question. They report several cases of late carcinomatous manifestations following resection wherein a report of benign hyperplasia was obtained following the usual microscopic examination. I have had one such case. These observers contend that, because of the perhaps more than occasional occurrence of insular prostatic carcinomas in which the usual signs are absent, routine serial study should be made of segregated sections; that the time and expense involved are justified even though but an occasional case of latent malignancy is disclosed when without such scrutinizing study it would not have been so diagnosed. One might also add with a measure of verity that late malignant growths are known to have occurred under similar circumstances following digital enucleation. It should also be remembered that prostatic tissue is not all removed in the usual open prostatectomy. On the credit side of resection it can be said that many patients with relatively early obstruction will submit to resection who would not accept open surgery; that in some at least of these cases, if an orderly painstaking serial study of removed tissue is made, an early malignant growth may be discovered and thereupon subjected to radical surgery. Here is Kramer's and Ritter's recommendation. They advise "that between seventy-five and 150 slides in the larger type of prostate be subjected to careful examination. At the time of operation it is also suggested that the tissue be segregated into five different areas." My counter proposal for purposes of practicality would be three such divisions: the midline area, one lateral lobe and the other lateral lobe. It would seem a reasonable expectation that, under such careful study following every resection, cases of insular or previously overlooked incipient malignant growths would thus come to early positive diagnosis and radical surgery.

Prostatic carcinoma in its earliest stage is a proper subject for radical perineal excision. When, however, they are well defined or extensive, the end result of this type of surgery scarcely justifies the procedure. The problem then is amelioration. Here resection again plays a valuable role. Many such patients may be carried along for a varying period of time in comparative comfort. One such patient comes to mind who, after five years and three resections, still devotes full time to his business pursuits and, to the unsuspecting observer, enjoys seeming good health.

The only supplemental physical agent that I employ in such cases is fractional roentgen therapy, and for several reasons. The pressing one is to obviate late secondary bleeding, a more than occasional observation in malignant conditions. In this connection it has been strikingly effective. Massive doses, however, should be interdicted. The other reason is for the alleviation of pain when present. Here again it is the most durably effective agent. The third is retardation, a term used advisedly as perhaps a bit more accurate than the euphemistic one of arrestation, so frequently enunciated by the proponents of physical therapy in the management of cancer of the genito-urinary tract.

It is evident from the foregoing somewhat sketchy commentary that the prostatic picture of today is far

removed from that of a generation or two past, and those over whose heads hang the portentous shadow of approaching senescence may peer in the nebulous future with considerably less apprehension than could their forbears.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING CHAPTER, WHICH IS THE SECOND OF A SERIES ON AMPUTATIONS AND ARTIFICIAL LIMBS TO APPEAR IN THIS COLUMN. WHEN COMPLETED, THIS SERIES WILL BE PUBLISHED IN THE FORM OF A HANDBOOK ON AMPUTATIONS. THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE COOPERATION OF ITS GROUP OF CONSULTANTS ON ARTIFICIAL LIMBS. THE COUNCIL IS REPRESENTED BY DRS. FRANK D. DICKSON, HARRY E. MOCK, FRANK R. OBER, S. PERRY ROGERS, PAUL STEELE AND PHILIP WILSON, AND THE ASSOCIATION OF LIMB MANUFACTURERS OF AMERICA IS REPRESENTED BY MESSRS. MCCARTHY HANGER SR., W. E. ISLE, JOSEPH A. SPIEVAK, DAVID E. STOLPE AND J. B. KORRADY.

HOWARD A. CARTER, Secretary.

CHAPTER II. GENERAL PRINCIPLES GOVERNING ALL AMPUTATIONS

1. INDICATIONS

There are three general indications for amputations: (1) acute trauma of sufficient severity to prohibit viability of a part of an extremity; (2) disease, including malignant neoplasm, infection which appears incurable locally and which threatens to destroy life, and gangrene due either to diabetes or to local circulatory failure; (3) chronic deformities, congenital or acquired, so disabling that better function can be assured by amputation than by any amount of reconstructive surgery and physical therapy. The type of operation indicated and the degree to which function of the stump may be anticipated are dependent somewhat on the cause for amputation.

A. Trauma.—If a part of an extremity is entirely severed or if it is absolutely apparent that it cannot be saved and restored to useful function, amputation should be performed immediately. Within the first six to twelve hours, during which the wounds may be grossly contaminated but the tissues are not infected, a clean operation can be performed at a site of election with a good chance of primary healing and a good functional stump. After this period of grace has expired the purpose of the amputation usually becomes the saving of life and all viable tissues rather than the creation of a permanent stump, and a secondary amputation is usually indicated when the condition of the limb and the patient permit. This late amputation may be carefully planned and should result in a good stump for functional purposes.

B. Disease.—The saving of life is frequently a paramount consideration in amputations performed for disease. If the surgeon, however, is fully aware of the types of operation most likely to assure a functional stump at the different levels, a good stump can frequently be secured without prejudicing the first consideration in any way.

C. Deformities.—Amputations of useless and seriously disabled extremities are always operations of election. The wishes of the patient can be considered, a thorough study of the possible sites and methods of operation can be made, and the limb-maker can be consulted before the amputation is performed. Every such operation should be clean surgery and every stump created should function well.

2. SURGICAL PRINCIPLES

Certain general surgical principles apply to amputations at any level. The bone must be dealt with in the way best calculated to allow it to withstand pressure without pain. Disarticulation leaves surfaces accustomed to pressure from contiguous bone. In amputations in the continuity of long bones the end is much more likely to withstand pressure if amputation is performed through the cancellous portion near either end than if it is performed through the middle portion where the cortex is thick and the medullary cavity is well defined. Osteoperiosteal procedures such as fusion of the tip of the os calcis to the sawed end of the tibia in the Pirogoff operation and the patella to the cut femur in the Gritti-Stokes operation are very successful if union is obtained, but attempts at similar procedures

Fig. 1.—Temporary leg with articulated foot and plaster socket for below-knee stump.

in the shaft portions of long bones are not recommended. The tendinoplastic procedures in the lower third of the leg and in the condylar region of the femur are extremely successful in providing painless stumps, capable of sustaining outside pressure. For amputations through the middle portions the "aperiosteal" treatment of the bone is strongly recommended. This consists in removing the periosteum for a distance of from one-half to 1 inch, smoothing off all rough edges from the cortex with a file or rasp and curetting out the medullary cavity for a distance of from one-half to 1 inch.

Proper treatment of the vessels and nerves is imperative. Major arteries must be isolated and carefully ligated. Opinions differ as to the choice between silk and chromic catgut, but with either material a ligature of large caliber and a measure of restraint in drawing it tight will insure against cutting through the vessel wall. Some surgeons prefer double ligations of major arteries. All important nerves should be injected with alcohol of 95 per cent to absolute strength and cut as high as is practicable without exerting strong tension. Careful injection of alcohol into the terminal portion of the nerve makes plastic procedures on the nerve stump unnecessary. Ligation of major nerves distal to the point of injection is advisable.

The problem of the amount and kind of soft tissues with which to cover the bone ends is important. Muscle tissue used for this purpose and subjected to pressure undergoes atrophy and is converted into scar tissue

which is often painful and tender. Broad tendons such as are available behind the lower half of the tibia and in front of the lower fourth of the femur make excellent coverings. Fascia is available everywhere and as covering is second in importance only to skin.

The placement of scars for optimal function of the stump is susceptible to rather definite rules. Plantar flaps provide superior function in amputations of part of the foot and in the osteoplastic and tendinoplastic amputations at the ankle. Anterior flaps are best everywhere between the lower tibia and upper femur. Posterior flaps are preferred when they are available in disarticulation of the hip. In the arm and forearm the end of the stump is subjected to no great amount of pressure, so terminal scars are quite satisfactory. In any situation the bone must be covered with freely movable normal skin with an adequate blood supply and not under tension. For function within a prosthesis, redundancy is as bad as tension. A flabby redundant pad of soft tissues over the end of the bone cannot be fitted well and serves no functional purpose.

3. POSTOPERATIVE CARE

A. *Traction*.—Postoperative skin fixation is advised as a routine procedure. In open amputations skin traction is imperative and should be maintained until healing of the wound is complete. In closed wounds traction is indicated when infection is present or anticipated or when the skin flaps are under considerable tension. Such traction is conveniently applied through wide adhesive straps over a suitable spreader. The many tailed bandage of Scultetus is a convenient and practical outer dressing.

B. *Drainage*.—Surgeons differ on the drainage of amputation wounds. The amount of uncontrolled bleeding and the health of the tissue flaps affect the judgment in each case on this point. If drains are placed, the soft rubber such as is used in making Penrose or cigaret drains is recommended. Precise tailoring of flaps combined with careful hemostasis and closure often renders drainage unnecessary.

C. *Splinting*.—Splinting of the postoperative stump serves two purposes: to restrain painful movements of the stump and to prevent contractures of joints. It also facilitates the application of snug bandaging. It is particularly important in leg amputations, in which the postoperative dressing should include a posterior splint from the upper thigh to a point several inches below the end of the leg stump.

D. *Physical Therapy*.—The amount and kind of physical therapy which may improve the function of an amputation stump depend on the type of amputation which has been performed and on the length of time which for one reason or another is allowed to elapse between the operation and the application of a permanent prosthesis. End bearing stumps may allow function in a permanent prosthesis within so few weeks that little treatment of the stump is needed. Stumps in which function of most of the remaining musculature is preserved will not shrink as much as stumps in which muscle atrophy of disuse is to be anticipated. Regular massage and the continuous wearing of a woven cotton elastic bandage serve to reduce the subcutaneous fat in a stump. Contrast baths, alcohol rubs and hot salt soaks are definitely useful in conditioning the skin and may be used as soon as the wound is healed. Early active motion preserves joint function and muscle tone. Splinting of joints between periods of exercise may be necessary to prevent contracture deformities. Healed

end bearing stumps should be given pressure exercises beginning within two weeks of amputation. In general the purpose is to begin active function, using some form of prosthesis at the earliest possible moment, and to apply such physical measures as may benefit the condition of the stump through the entire period until the patient is thoroughly accustomed to his permanent appliance.

4. THE TEMPORARY PROSTHESIS

Whenever possible the permanent prosthesis for an amputation should be planned and arranged for at the earliest practicable moment. Just as the duties of the surgeon performing an amputation as a life saving measure include the refashioning of the stump at a later date if necessary, so they include supervision of the

permanent socket can be fitted successfully. It also hastens the inevitable pressure atrophy caused by the use of an artificial limb. It is indicated only for the conical stump which may be inserted and withdrawn through the top of the socket. It does not meet the mechanical problems of alinement, weight bearing and motion, and its use may produce faulty habits difficult to correct after a permanent prosthesis has been fitted.

For below knee amputations a simple type of temporary prosthesis (fig. 2) can be obtained from the limb manufacturers at small cost, which is to be fitted to the patient's stump by means of a plaster of paris socket applied by the surgeon. This prosthesis is equipped with an articulated foot, movable knee joint and a canvas or leather thigh corset. In expert hands such prostheses

Fig. 2.—Diagram showing construction of skeleton leg for below-knee amputation.

patient until he has mastered the use of a permanent prosthesis. Unnecessary delay results not only in faulty psychologic adjustment and habits but in joint contracture and atrophy of the stump.

The degree of atrophy inevitable in an amputation stump depends largely on the amount of adipose tissue and functionless muscle tissue left in the stump. Nevertheless, all stumps shrink to a greater or less degree, and thus emerges the dilemma between the recognized advantages of early function and the objection that the original socket will no longer fit after the atrophy has occurred.

One escape from this dilemma is the use of a temporary pylon constructed by the surgeon, consisting of a plaster of paris socket lined with felt, mounted on a sawed off crutch and slung by straps from the shoulders or waist. This contrivance (fig. 1) rids the patient of the crutch habit at an early date, minimizes the contracture and wasting of the extremity from disuse, and reduces the bearing surface of the stump so that a

have frequently been fitted as early as from two to three weeks after amputation.

A third alternative is the use of a complete temporary prosthesis fitted by the limb manufacturer. Such an appliance might be expected to meet the requirements of alinement, motion and balance, but to do so makes its cost almost prohibitive. The provision of a temporary appliance at no charge aside from the cost of the permanent prosthesis has been used by some manufacturers as a method of sales promotion not beyond question from the ethical standpoint. A more salutary practice is the fitting of a permanent prosthesis at the earliest possible date, with the provision of a new socket within a few months if that becomes necessary when the inevitable atrophy has occurred. The cost of this method is relatively small.

In any case the prolonged "shrinking" of the stump by tight bandaging over many months is to be condemned. The advantage in permanent fitting is overshadowed by the physical and psychologic evils of disuse

IMMUNOLOGIC STUDIES OF POLIOMYELITIS

Numerous recent studies on the immunologic reactions of the poliomyelitis virus have resulted in a considerable extension of knowledge of its behavior. The expensive and somewhat cumbersome procedure of carrying out virus neutralization tests in monkeys to gain information which in most other infectious diseases could be derived from an equal number of test tubes or mice has resulted in efforts to devise a more satisfactory procedure. Recently Raffel and Schultz¹ endeavored to demonstrate a direct reaction between antigen and antibody along more practical lines. Their investigations were divided into four groups: experiments to demonstrate a reaction between virus and immune serums in vivo and in vitro, experiments to demonstrate a changed antigenic specificity of infected monkey cords in reactions with neutralizing serums and with anti-cord serums produced in rabbits, experiments on the obscure Schwartzman-Sanarelli reaction and studies on the heterogenic relationship between the virus or products of viral activity and the erythrocytes of various animal species. The studies involved a series of immunologic methods most of which had not been previously employed but all of which were aimed at eliciting a specific reaction based on an antibody or antigen derived from animals infected with poliomyelitis or convalescent. The technics employed included anaphylaxis in the guinea pig, the use of guinea pig and monkey uterine strips, cutaneous tests in monkeys and precipitative and complement fixation reactions. When the results were added to previous unsuccessful attempts to demonstrate specific precipitin, complement fixation and cutaneous reactions and to those experiments which have eliminated the possibility of the occurrence of a specific soluble antigen during the acute phase of the disease it was obvious that, aside from the neutralization test, the hope for a specific immunologic reaction for poliomyelitis is somewhat remote. Barring therefore the development of some more pro-

ductive line of research, reliance must continue to be placed on the virus neutralization test in spite of its disadvantages.

Successful adaptation of human poliomyelitis virus to the cotton rat and white mouse is one of the most promising advances in practical research technic of the present decade. Earlier apparently monkeys were the only susceptible animal species until Armstrong² reported transference of rhesus poliomyelitis virus to the eastern cotton rat. The disease thus produced in cotton rats was characterized by flaccid paralyses of the extremities associated with degenerative lesions of the anterior horn cells,³ these lesions being apparently identical with those usually observed in human poliomyelitis and in experimental poliomyelitis in monkeys. The identity of the rodent disease with rhesus poliomyelitis was further indicated by the fact that the rodent infection would produce typical poliomyelitic symptoms and lesions on return inoculation into monkeys.

It was afterward reported by Armstrong⁴ that the rhesus virus once serially adapted to the cotton rat could be successfully transferred to white mice. Proof of this transference, however, was incomplete, since it was found that the mouse virus was nonpathogenic on return inoculation into monkeys. This loss of pathogenicity suggested that the human poliomyelitis virus might have been lost, the observed symptoms in mice being due to some unknown neurotropic environmental virus. Such mouse viruses are known to be omnipresent in certain environments and have been recently studied in detail by Theiler⁵ and Olitsky.⁶

In order to complete the proof of the successful transference of the human virus to mice, Jungeblut and Sanders⁷ have more recently studied the antigenic properties of the passage virus directly isolated from the mouse brain and cord or after propagation in mouse tissue culture. Three successful mouse transferences of the SK New Haven strain of poliomyelitis virus were made by the Columbia University bacteriologists. Confirming earlier investigators, Jungeblut and Sanders found that on serial inoculation into the cotton rat the human virus rapidly lost its pathogenicity for monkeys. Simultaneously with this attenuation for the rhesus monkey there was an increase in rodent pathogenicity. Still further increases were noted in the mouse till a "fixed" virus was eventually obtained, wholly nonpathogenic for monkeys. This fixed virus could be successfully propagated in mouse tissue cultures, embryonic mouse brain in ox serum ultrafiltrate being the most effective culture medium.⁸

The immunochemical specificity of the fixed mouse (murine) virus was titrated against numerous specific antiviral serums. Serum-virus mixtures were incubated for ninety minutes at 37 C. and then titrated for unneutralized virus by serial intracerebral inoculations into white mice. Normal human, horse and monkey serums used as controls gave no suggestion of neutralization. Monkey convalescent serum, human convalescent serum and poliomyelitis immune horse serum gave partial or complete neutralization, the highest neutralizing titer being obtained with the pseudoglobulin fraction of homologous poliomyelitis immune horse serum. The serologic data presented by Jungeblut and Sanders leave little doubt that the human virus has been successfully transmitted and adapted to mice, by preliminary serial passage through monkeys and cotton rats.

The most encouraging results, however, have been the claimed successful immunization of monkeys by repeated subcutaneous injections with living mouse virus. This specifically attenuated viable murine vaccine is readily grown in artificial tissue cultures. While the immunity conferred by this viable vaccine is not absolute, it is sufficiently effective to stimulate optimism for further clinical research. If the Jungeblut murine vaccine should eventually prove to be clinically effective, Armstrong's initial observation of 1939 may prove to be one of the major discoveries of modern research medicine.

RHEUMATIC HEART DISEASE IN PHILADELPHIA HOSPITALS

Recently Hedley¹ of the United States Public Health Service reported the results of an extensive survey of cases of rheumatic heart disease in Philadelphia hospitals. This report covered a study of more than 4,600 cases of rheumatic heart disease, rheumatic fever, Sydenham's chorea and subacute bacterial endocarditis in hospitals of this area in the years 1930-1934 inclusive. Hedley's report includes an analysis of the age, race and sex distribution of the conditions mentioned as well as information on their interrelationship.

The importance of rheumatic heart disease as a problem of youth and early adulthood cannot be overemphasized. The onset in 69.1 per cent of the cases of rheumatic heart disease, as well as in 76.4 per cent of rheumatic fever and in 98.2 per cent of chorea, occurred before the age of 20 years. This large scale study shows, furthermore, that the peak of the onset of rheumatic fever, Sydenham's chorea and rheumatic heart disease occurred in the 5 to 9 year age period, the conditions being relatively uncommon in children under 5 years of age. Moreover, the onset of rheumatic fever and rheumatic heart disease in persons over 40 years of age was encountered in only a small percentage of cases. As indicated by Hedley, rheumatic heart disease, unlike some other types of heart disease, is not

a problem of great importance among older persons. The data with respect to more than 3,600 cases of rheumatic heart disease would tend to confirm the belief of most investigators that the condition is somewhat more common in females than in males, almost three fifths of the observed cases occurring in the female. This preponderance of cases in females was noted in all age groups except that of 15 to 19 years, in which period the number of cases in the two sexes was about equal. In agreement with most investigators, it was likewise noted that nearly twice as many cases of Sydenham's chorea were encountered in females as in males. About the same number of male and female patients were admitted for rheumatic fever.

About 13 per cent of patients with rheumatic heart disease were Negroes. Although this figure is in proportion to the size of the Negro population of Philadelphia, Hedley suggests that rheumatic heart disease is perhaps less common among Negroes than among white persons; owing to the less favorable economic status of the Negroes (50 per cent of the colored population being on relief) they are more likely to be hospitalized for rheumatic heart disease than are white persons. In any event a more extensive survey would be necessary to elucidate this point.

Observations made on the interrelation of rheumatic heart disease, rheumatic fever and Sydenham's chorea are interesting. Some 61 per cent of the cases of rheumatic heart disease included in the study gave histories of rheumatic fever or exhibited clinical manifestations of the latter condition, while Sydenham's chorea, with or without rheumatic fever, was indicated in slightly more than 15 per cent of the cases. Diagnoses indicated the presence of rheumatic heart disease in 42 per cent of the cases of Sydenham's chorea, and this figure would probably have been larger had the cases been followed after release from the hospital. Anyway these data, together with similar reports in the literature, indicate that the likelihood of developing rheumatic heart disease is much greater for a child with Sydenham's chorea than for one who has never had this condition. Almost 23 per cent of more than 3,600 cases of rheumatic heart disease, including cases complicated by subacute bacterial endocarditis, gave clinical evidence of rheumatic arthritis. More than 80 per cent of the patients under 20 years of age were regarded by Hedley as having active rheumatic infection. This investigator² has also pointed out that among persons under 30 years of age more than 75 per cent of the deaths from rheumatic heart disease are apparently attributable to active rheumatic infection.

Hedley's survey is particularly noteworthy because of the large number of cases on which it is based. It is restricted, however, to a single locality and might well be supplemented by similar extensive surveys made elsewhere. Thus the influence of factors peculiar to a restricted area would be as nearly as possible eliminated.

PAN AMERICAN HEALTH DAY

For nearly four decades the American republics have cooperated systematically in the prevention of the international spread of disease.¹ During the last two decades this cooperation has been made both more effective and extensive. In order to give this hemispheric relationship a more efficient and stable basis, the Pan American Sanitary Bureau was created in 1902. It is the oldest of the great international health bodies and practically the only one functioning at present.

Authority for the work of the bureau, which has grown from a purely advisory role in quarantine matters to an active interest in many health problems, is contained in the Pan American Sanitary Code adopted in Habana in 1924 and ratified by all the American republics, the first inter-American treaty to enjoy this distinction. During the years of its existence, the bureau has received constantly increasing support and financial assistance from the different republics.

Among the recent cooperative activities undertaken by the bureau² have been arrangements for international health conferences and representation at important meetings; health exhibits; organization of technical committees to study such problems as nutrition, malaria and health legislation; granting of scholarships; field work in plague control, poliomyelitis campaign, water supplies, sewage disposal, hospital organization, vital statistics, promotion of cultural relations; collection and dissemination of epidemiologic information; publication of the monthly bulletin and other literature including weekly statistics of disease prevalence; answering inquiries on public health and medical questions; furnishing aid in the case of catastrophes such as earthquakes; translating into Spanish the U. S. Pharmacopeia and allied material; distribution of bacterial cultures and biologic standards. Above all, however, stress has been laid on promotion of international cooperation in health matters and maintenance of relationship with various national health authorities.

In recognition of the success of these decades of inter-American health and medical cooperation, the fourth Pan American Conference of National Directors of Health resolved in May 1940 that Pan American Health Day should be celebrated every year in all the American republics. The date chosen for this purpose, December 2, was, in 1902, the date of the first Pan American Sanitary Conference in Washington. Decrees have already been issued in practically all the American republics proclaiming this day as Pan American Health Day. A similar proclamation is under consideration by the President of the United States, favorable action having been recommended by the Federal Security Administrator, the Secretary of State and the director of the Pan American Sanitary Bureau.

The celebration will have a twofold purpose: first, to commemorate what Pan American cooperation has achieved in health during the last few decades, recalling incidentally those great men who in all the American republics have done so much to promote public health and, second, to center attention on the teaching of preventive principles and practices and to rededicate all hearts to the great cause of public health and Pan Americanism. Elaborate arrangements have been made in practically all the American republics for the celebration of this day on a national scale, through the cooperation of health and educational authorities, national societies, the press, radio and similar agencies. Even outside its public health connections, the medical profession is going to take a leading part in the celebration. The academies of medicine of Colombia, Mexico and Peru are preparing official ceremonies. The plans for celebration in the United States include a radio program on December 2 in which representatives of leading medical and other scientific societies will participate.

Amid the troubles of this distracted world, all the nations in the American hemisphere, from the St. Lawrence River to Cape Horn, will unite in recalling the permanent blessings of peace and health. For this purpose international cooperation and understanding are essential. The physicians of the United States, who have always encouraged this movement for closer scientific relations among the American nations, will be pleased to join again in approval of this activity.

THIRD ANNUAL CONGRESS ON
INDUSTRIAL HEALTH

Industrial health is of exceptional interest at this time when national preparedness depends so greatly on industrial production. The attention of physicians is called to the program of the Annual Congress on Industrial Health published in the Organization Section in this issue. This will be the third of these meetings sponsored by the Council on Industrial Health of the American Medical Association. They are designed to acquaint the physician and others with the rapidly expanding importance of preventive medicine and surgery applied to industrial organization.

Since every man hour of production is vital at this time, the program of the congress is intended to be as helpful as possible to physicians called on to control those factors which in the past have contributed greatly to the incidence and costs of industrial absenteeism. In the field of trauma the hand and the eye have proved to be particularly vulnerable. Symposia have therefore been developed to present the best current opinion on the management of these costly forms of industrial disability. Of the occupational diseases, dermatitis has long been recognized as the most troublesome. A series of demonstrations has been planned to include discussion of the criteria for diagnosis of industrial cutaneous

2. Annual Report of the Director, Pan American Sanitary Bureau, 1939-1940.

disorders as well as accepted methods for the treatment and placement of susceptible employees. Among non-occupational diseases the common cold and influenza annually exact an enormous toll through loss of earning capacity and disruption of production schedules. This problem also will be discussed from the point of view of the essential economics, the possibilities of control through air conditioning and the role of the physician in industry and in private practice. Since many able-bodied men will probably be inducted into military service, industry may need to recruit workers from the physically handicapped and from the aging groups. These developments, of enormous medical and social significance, will be featured at the congress. Assignment of this type of worker into industry with proper consideration of physical ability and mental aptitude will be fully considered. Concern has been expressed about the availability of trained personnel in industrial health, the subject of an early resolution by the Committee on Medical Preparedness of the American Medical Association. A session will be devoted to determining what shortages exist and the best means for correction. It is hoped that concrete proposals for better training for the industrial nurse, the industrial hygienist, the safety engineer and the physician in industry may grow out of these discussions. A means will also be provided for the interchange of experience and results of recent activity by committees on industrial health in state and county medical societies.

The congress promises to provide an unusual opportunity to the medical profession to grasp a sense of its potential contribution to improved physical well-being among the employed population.

Current Comment

NARCOTIC PEDLERS IMPOSE ON PHYSICIANS' WIDOWS

From the Bureau of Narcotics in Washington comes a warning from the Commissioner, Mr. H. J. Anslinger, which should be widely disseminated among physicians and their families. Illicit traffickers in narcotics have in some instances recently developed a technic with which they were able to swindle either the widows or members of the families of physicians who had recently died. Apparently these peddlers watched the daily papers for the notices of deaths of physicians. Shortly after the publication of such a notice of death the trafficker appeared and represented himself to be "a narcotic appraiser," stating that he represented a federal agency and seeking to induce the survivors of the physician to turn over to him whatever narcotics might be found among the effects of the deceased. Thus far attempts have been made only on the families of physicians. It seems probable, however, that a similar attempt might be made in connection with stocks of narcotics held by druggists. Physicians and druggists everywhere should be warned against this type of fraud.

TUMORS IN TWINS

Macklin¹ recently appealed to physicians through medical journals for reports of cases of tumors in twins. Twenty case reports were thus obtained, seventeen of which had not been included previously in the literature. The author collected from the literature reports of fifty-three pairs of monozygous twins and thirty-five pairs of dizygous twins in which tumors occurred in either one or both twins. The newly discovered cases, together with those previously reported, were analyzed. It was found that tumors affect both members of a monozygous twin pair far more frequently than they affect both members of a dizygous twin pair. The tumor was of the same type and occurred in the same organ much more frequently in the monozygous than in the dizygous twin group. The age of onset of the tumors was more nearly identical in the monozygous than in the dizygous twins. The average difference in age of onset of the tumors in several pairs of identical twins in which both twins were affected was only 0.6 year, whereas in the fraternal twin pairs in which both twins were affected with tumors the average time elapsing between the ages of onset was 2.9 years, or five times as long. These observations appear to indicate that heredity plays an important part in tumor production and in the age of onset.

CARCINOGENIC LIPOID IN HUMAN CANCER

The extraction of a fat-soluble carcinogenic factor from primary breast cancer of man has been reported recently by Menke¹ of the Department of Surgery, Stanford University School of Medicine. Two primary carcinomas of the breast were excised by the Stanford surgeons, ground to a hash and subjected to repeated extraction with fat solvents in a Soxhlet apparatus. Acetone, ethyl ether, purified petroleum benzine and absolute ethyl alcohol were used in the order mentioned. The four extracts thus obtained from each tumor were pooled and evaporated to dryness, and samples of the resulting products were injected subcutaneously in the lower mammary region of virgin female mice. One tumor mass developed at the site of the injection in each series. The masses became palpable between the 229th and the 282d day and grew rapidly after this date, reaching about 2 cm. in diameter in from two to three weeks. At this stage each new growth was firmly adherent to and had already penetrated the abdominal walls. Gross metastases were not found. Histologically each tumor was a spindle cell sarcoma. Fragments transplanted to normal mice grew rapidly. Each transplant resulted in a 2 cm. ulcerating mass by the twentieth day. Spontaneous tumors failed to occur in 200 control mice during the course of the investigation. The chemical nature of this newly discovered human carcinogenic lipid and its possible antigenic properties are now under investigation.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

THE NAVAL RESERVE

The Secretary of the Navy has stated that naval reservists are serving in practically every type of ship of the fleet and in administrative duties ashore. Since the emergency proclamation by the President, Sept. 8, 1939, the officers and men of the Naval Reserve, excepting men of the Fleet Reserve, have reported for duty on a voluntary basis. The rapid acquisition of ships for auxiliaries, patrol and harbor defense duties necessitated, however, placing the organized Naval Reserve on a compulsory basis, which the Secretary of the Navy did October 5. The Navy Department indicated that, as of Oct. 26, 1940, 2,500 Naval Reserve officers of all classes were on duty and 4,000 enlisted men, not including the Fleet Reserve.

The Naval Reserve has numerous projects under way at this time, giving officers and men special training, with active duty available for all candidates who volunteer on completion of the courses. Among the classes for officers are flight aviation medicine at Pensacola, Fla., supply corps school at Washington, D. C., chemical warfare school at Edgewood Arsenal, Maryland, industrial procurement at the Army War College, merchant marine training centers in New York and San Francisco, the harbor defense school at Boston, for the training of engineer officers of organized divisions assigned to local defense duties and the Naval Reserve midshipmen schools, aboard the U. S. S. *Illinois*, New York, and at Abbott Hall, Northwestern University, Chicago. The last two schools are part of the Navy's program to train approximately 4,000 line ensigns of the Naval Reserve qualified for duty afloat. A third school will be opened at the Naval Academy in February 1941.

MEDICAL SUPPLIES FOR ENGLAND

The Medical and Surgical Supply Committee of America, with headquarters at 420 Lexington Avenue, New York, comprising 265 physicians throughout the United States, was formed last August to secure medical supplies to be sent overseas for aid to the civilian population in England. The committee announces that already more than \$40,000 in medical and surgical supplies has been shipped abroad. Among the supplies donated were a portable x-ray machine, a portable anesthesia unit, five barrels of surgical instruments, diamond earrings valued at \$1,000 to be converted into cash to purchase medical equipment, and an operating kit valued at \$400. Druggists and pharmaceutical and supply houses have sent thousands of hypodermic needles valued at \$7,000, Luer syringes, large quantities of bandage, drugs, hundreds of surgeon's gloves, and other valuable equipment.

Another organization, Bundles for Britain, Inc., 29 West 57th Street, New York, has formed a medical and surgical supply department, but it is in no way affiliated with the Medical and Surgical Supplies Committee of America, the executive chairman of which is

Mrs. Ronald B. Balcom. The sole function of the Medical and Surgical Supply Committee of America is to assemble medical supplies and instruments from donors, to inspect the material, restore the surgical instruments, and then ship them abroad for use in emergency hospitals and field units in Great Britain.

OHIO CHIEF OF SELECTIVE SERVICE

Dr. Howard E. Boucher, Columbus, lieutenant colonel and executive officer of the 112th Medical Regiment, Ohio National Guard, has been appointed chief medical officer of Selective Service in Ohio. There will be three medical induction centers in Ohio: Fort Hayes at Columbus, and at Toledo and Cleveland. The Committee on Medical Preparedness has furnished to the governor a list of qualified physicians for positions as medical examiners and alternate examiners for the 330 local draft boards.

NATIONAL DEFENSE NIGHT

The program of the Philadelphia County Medical Society, Philadelphia, November 13, was devoted to national defense. The speakers were Dr. William DeKleine, Washington, D. C., medical director, American Red Cross, on "Red Cross Participation in Medical Defense"; Brig. Gen. Leigh C. Fairbank, chief, Dental Corps, U. S. Army, Washington, D. C., "The Part Dentists Play in National Defense," and Rear Admiral Adolphus E. Watson, commandant, Fourth Naval District, Philadelphia, "The Navy Ashore." Certificates were conferred on members in practice for fifty years. The program was presented in collaboration with the W. W. Keen chapter, Association of Military Surgeons of the United States.

LECTURES ON MILITARY MEDICINE

Recent lectures in the series on military medicine sponsored by the Philadelphia County Medical Society are as follows:

Dr. Isidor S. Ravdin, *Advances in Therapeutics as Related to War Surgery*, October 17.

Major James B. Mason, Medical Corps, U. S. Army, *Tissue Reaction to Missiles of War—Ballistics*; also Dr. William Bates, *The Surgery of War as Contrasted with Industrial Surgery*, October 24.

Dr. Robert H. Ivy, *Maxillofacial and Reconstructive Surgery in War*, October 31.

Dr. Max M. Strumia, *Transfusions of Blood and Hematologic Substitutes in Advanced Medical Installations in War*, November 7.

The present series of thirteen lectures ends early in December; another series will follow shortly thereafter.

The society recently reported that 1,212 questionnaires have been returned to its office from those sent out to obtain data concerning availability of local phy-

sicians for service in the event of a national emergency. Of this number 729 were from members of the society and 483 from nonmembers. There are about 4,200 physicians in Philadelphia, it was pointed out.

AMERICAN MOBILIZATIONS

According to a statistical study made by the U. S. Veterans' Administration, Washington, D. C., America mobilized 350,000 men for the American Revolutionary War, 527,650 for the war of 1812, 107,631 for the war with Mexico, 2,128,948 (Union forces only) for the Civil War, 280,564 for the Spanish-American War, 130,000 for the Indian wars and 4,791,172 for the World War. The average age of the World War

doughboy, according to the Associated Press in commenting on the foregoing statistics, is now 47 years and of the Spanish-American veteran 65. The Civil War campaigner averages 95. The Veterans' Administration statistical study shows that 4,041,017 World War veterans were living at the beginning of 1940.

PSYCHIATRIC PROBLEMS

A symposium on psychiatric problems concerning military conscription was presented before the Medical Society of St. Elizabeths Hospital, Washington, October 22; the speakers were Capt. Dallas G. Sutton, U. S. Navy, Lieut. Col. William C. Porter, U. S. Army, and Dr. Harry Stack Sullivan.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

FIRST CORPS AREA

The following medical reserve officers have been ordered to extended active duty with the regular army by headquarters of the First Corps Area, which comprises the states of Maine, Massachusetts, Connecticut, New Hampshire, Vermont and Rhode Island:

ALLEN, Eugene E., 1st Lieut., Milford, Mass.
ALPERT, George R., 1st Lieut., Brookline, Mass.
ANDERSON, Karl V., 1st Lieut., Derby, Maine.
ANDREN, Henry E., 1st Lieut., Boston.
ASCHER, David S., 1st Lieut., Boston.
BACHRACH, Samuel, 1st Lieut., Maynard, Mass.
BARALD, Fred C., 1st Lieut., New Haven, Conn.
BOYER, Samuel H., 1st Lieut., Winchester, Mass.
BURKE, Jacob B., 1st Lieut., Chelsea, Mass.
CARPENTIERI, Anthony L., 1st Lieut., New Haven, Conn.
CASERTA, Silvio J., 1st Lieut., Bridgeport, Conn.
CLOUGH, Herbert T. Jr., 1st Lieut., Bangor, Maine.
CORCORAN, John J., 1st Lieut., West Roxbury, Mass.
DONAGHY, George E., 1st Lieut., Boston.
DORFMAN, Jacob, 1st Lieut., Hartford, Conn.
EGAN, William J., 1st Lieut., Dorchester, Mass.
FICICCHY, John Jr., 1st Lieut., Hyde Park, Mass.
FOLEY, John J., 1st Lieut., Malden, Mass.
FOX, Lester I., 1st Lieut., Quincy, Mass.
FREEDMAN, Stanley S., 1st Lieut., Providence, R. I.

GARDINER, Harry M., 1st Lieut., Harding, Mass.
GOLDMAN, Max, 1st Lieut., Boston.
GRIFFIN, Julian P., 1st Lieut., Indian Orchard, Mass.
HEIFETZ, Ralph, 1st Lieut., Portland, Maine.
HYDE, Robert W., 1st Lieut., Fairfax, Vt.
JACOBS, Harry, 1st Lieut., Concord, Mass.
JOHNSON, Paul E., 1st Lieut., Attleboro, Mass.
KASPARIAN, Karl D., 1st Lieut., Dorchester, Mass.
LEVINE, Samuel, Captain, Lynn, Mass.
McCABE, George E., 1st Lieut., Arlington, Mass.
McCARTHY, Robert J., 1st Lieut., Dorchester, Mass.
McWETHY, Wilson H., 1st Lieut., Augusta, Maine.
MERLIN, Samuel A., Captain, Dorchester, Mass.
MOSKOVITZ, Abraham J., 1st Lieut., Burlington, Vt.
ROBEY, Nathaniel C., Captain, Newton Centre, Mass.
ROGELL, David, 1st Lieut., Warren, R. I.
ROSEN, Daniel, 1st Lieut., Roxbury, Mass.
RUBIN, Abraham, 1st Lieut., Pittsfield, Mass.
RUBINO, Bernard C., 1st Lieut., Baldwinsville, Mass.
SILVER, Gershon B., 1st Lieut., Hartford, Conn.
SINCLAIR, Edmond B., 1st Lieut., Providence, R. I.
STANKARD, William F., 1st Lieut., Stamford, Conn.
SWANN, William K. Jr., 1st Lieut., Boston.
TEMPLE, Francis E., 1st Lieut., Providence, R. I.
THOMAS, John M. Jr., 1st Lieut., Woodstock, Vt.
WIENER, Harry J., 1st Lieut., Revere, Mass.
WIEMERS, Eugene L., 1st Lieut., Concord, N. H.
ZELTZERMAN, Israel, 1st Lieut., Foxboro, Mass.

THIRD CORPS AREA

The following medical reserve corps officers have been ordered to extended active duty by the commanding general of the Third Corps Area, which includes the states of Pennsylvania, Virginia, the District of Columbia and Maryland:

BOYCE, Bingham, Captain, Bridgeville, Pa.
BRYLAWSKI, Michael, 1st Lieut., Philadelphia.
BUSH, Herman, 1st Lieut., Beaver Falls, Pa.
CARROLL, Edward Joseph, Jr., Captain, Pittsburgh.
COHEN, Max Harry, 1st Lieut., Washington, D. C.
COVALESKY, Victor John, 1st Lieut., Allentown, Pa.
DIXON, Joseph Moore, Captain, Roanoke, Va.
DELP, Charles William, Captain, St. Clair, Pa.
ERHARD, Elmo Enos, Captain, Curwensville, Pa.
FLUEGEL, Gerald Nicholas, Captain, Wilkes-Barre, Pa.
GERWIG, Walter Henry, Jr., 1st Lieut., Baltimore.
GORDON, Armand Byron, 1st Lieut., Washington, D. C.

HARRISON, Malcolm D., 1st Lieut., Washington, D. C.
JANJIGIAN, Edward Rupen, 1st Lieut., Danville, Pa.
KIRK, Milo Miller, 1st Lieut., Pittsburgh.
MANSFIELD, William Kenneth, 1st Lieut., Baltimore.
MASON, James B., Major, Philadelphia.
McLAUGHLIN, William B., Captain, Pittsburgh.
MILLIGAN, Alexander McLeod, Lieut. Col., Pittsburgh.
MOGAN, Christopher Joseph, Captain, Philadelphia.
SCHUBART, George Rudolph, 1st Lieut., Drexel Hill, Pa.
SHOWALTER, Josiah Thomas, 1st Lieut., Cambria, Va.
SONES, Maurice, 1st Lieut., Philadelphia.
STEIN, Arthur Julian, 1st Lieut., Philadelphia.
THOMAS, Preston Whitney, 1st Lieut., Pittsburgh.
TOLSTOI, George, 1st Lieut., Washington, D. C.
UHDE, George Irvin, 1st Lieut., Kennett Square, Pa.
URBAITIS, John Charles, Captain, Frankford, Pa.
VAN BUSKIRK, Frederick William, 1st Lieut., Pottstown, Pa.
WEST, George Brooks, Lieut. Col., Norfolk, Va.
WHITE, George Seese, 1st Lieut., Uniontown, Pa.
YINGLING, Paul Louis, 1st Lieut., Shippensburg, Pa.

FOURTH CORPS AREA

The following medical reserve corps officers have been ordered to extended active duty by the commanding general of the Fourth Corps Area, which includes the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana. Their rank, home address and station are indicated.

AARON, George, 1st Lieut., New Orleans, Camp Blanding, Fla.
ADAMS, Edward N., Captain, Florence, S. C., Savannah Anti-Aircraft Firing Center, Savannah, Ga.
ASKEW, Rufus A., 1st Lieut., Atlanta, Ga., Fort Bragg, N. C.

HAVERSTOCK, Richard T., 1st Lieut., Seattle, Fort Lewis, Wash.
HICKMAN, Harry S., 1st Lieut., Davenport, Wash., Fort Lewis, Wash.
HOLTZ, Paul Roscoe, Major, Lander, Wyo., 3d Military Area, Salt Lake City.
HORWITZ, Emanuel, Captain, Alcatraz Island, Calif., Fort McDowell, Calif.
HUNTINGTON, William H., Lieut. Col., Portland, Ore., Fort Lewis, Wash.

ISAAC, Ralph W., 1st Lieut., Pomeroy, Wash., Vancouver Barracks, Wash.
JACKEMY, Edward J., 1st Lieut., Oakland, Calif., Presidio of Monterey and Fort Ord, Calif.
JUMBLATT, Albert, Captain, Pacific Beach, Calif., Fort Rosecrans, Calif.
KINGSTON, George R., 1st Lieut., Wenatchee, Wash., Fort Lewis, Wash.
KONIGSBERG, Jerome, 1st Lieut., San Francisco, Presidio of Monterey and Fort Ord, Calif.
LARSON, Rudolph V., Captain, Smithfield, Utah, Fort Lewis, Wash.
LEE, George F., Captain, Union, Ore., Fort Stevens, Ore.
LEVAN, Norman E., 1st Lieut., Los Angeles, 1st Military Area, Presidio of San Francisco.
LIND, Laurie P., Major, Portland, Ore., 2d Military Area.
LLOYD, Robert E., 1st Lieut., San Francisco, Fort Lewis, Wash.
MAQUIRE, Joseph F., 1st Lieut., Ventura, Calif., Presidio of Monterey and Fort Ord, Calif.
McDONALD, Frank J., Captain, Bakersfield, Calif., Presidio of Monterey and Fort Ord, Calif.
MELLO, Henry G., 1st Lieut., Alameda, Calif., Presidio of Monterey and Fort Ord, Calif.
NELSON, Walfred A., 1st Lieut., Salt Lake City, Salt Lake City, Utah, Recruiting Officer.
NEWSON, Samuel J., Captain, Walla Walla, Wash., Fort Worden, Wash.
OHLMACHER, Joseph P., 1st Lieut., Missoula, Mont., Fort Lewis, Wash.
OSGOOD, Samuel B., 1st Lieut., Grants Pass, Ore., Presidio of Monterey and Fort Ord, Calif.
PEDERSEN, Christian B., Major, Tahoe, Calif., 1st Military Area.
QUALHEIM, Clarence B., Captain, Seattle, Fort Lewis, Wash.
RICH, David R., 1st Lieut., La Grande, Ore., Fort Lewis, Wash.
ROBBINS, Carl William, Lieut. Col., Eugene, Ore., Fort Lewis, Wash.
ROGERS, Thomas J., 1st Lieut., Los Angeles, Presidio of Monterey and Fort Ord, Calif.
SAWYER, Malcolm H., 1st Lieut., North Twin Falls, Idaho, 3d Military Area.
SENER, Walter P., Captain, San Francisco, 1st Military Area.
SHAEFER, J. H., Lieut. Col., San Francisco, Surgeon's Office, Hq. Ninth Corps Area, Presidio of San Francisco.
SHARP, Paul W., 1st Lieut., Klamath Falls, Ore., Fort Lewis, Wash.
SHIER, Cyril W., Captain, Arcadia, Calif., Presidio of Monterey and Fort Ord, Calif.
SIRBU, Abraham B., 1st Lieut., San Francisco, Presidio of Monterey and Fort Ord, Calif.
SPRAGUE, Norman F., 1st Lieut., Beverly Hills, Calif., Presidio of Monterey and Fort Ord, Calif.
STRANQUIST, Henry C., Major, Ogden, Utah, 3d Military Area.
SZUKALSKI, Joseph P., 1st Lieut., Pasadena, Calif., 1st Military Area, Presidio of San Francisco.
TEN EYCK, Thomas G., Captain, Portland, Ore., Fort Lewis, Wash.
THOMAS, Leon B., Captain, Vancouver, Wash., Fort Lewis, Wash.
THOMPSON, Roger S., Captain, Seattle, Camp Murray, Wash.
TICHENOR, Ernest LaPoint, Captain, Fort Belknap, Harlem, Mont., 3d Military Area, Salt Lake City.
TOPPENBERG, David R., 1st Lieut., Loma Linda, Calif., Presidio of Monterey and Fort Ord, Calif.
VELONIS, Stamatis G., 1st Lieut., Nespelem, Wash., Fort Lewis, Wash.
VOGT, Paul R., 1st Lieut., The Dalles, Ore., Fort Lewis, Wash.
WHITAKER, Clifford W., Major, Tacoma, Wash., 2d Military Area, Portland, Ore.
WHITE, Alfred S., 1st Lieut., San Francisco, Presidio of Monterey and Fort Ord, Calif.
WOLF, Robert W., 1st Lieut., San Francisco, Presidio of San Francisco.
ZENER, Francis B., Major, Portland, Ore., Vancouver Barracks, Wash.

RESERVE PUBLIC HEALTH OFFICERS

The following physicians have taken their oaths as assistant surgeons in the reserve of the U. S. Public Health Service. Their home address and medical schools from which they graduated are indicated:

ALDRICH, Clarence K., New York, Northwestern University.
BEARDSLEY, Wayne P., Staten Island, N. Y., Jefferson Medical College.
BERKEBILE, Robert D., Cleveland, Ohio State University.
CARSTENSEN, Vincent H., New Orleans, State University of Iowa.
CRAWFORD, John G., Charlottesville, Va., University of Virginia.
FRAGIN, Irving D., New York, New York University.
FARBER, David N., Staten Island, N. Y., Ohio State University.
FORAKER, Alvan G., Pittsburgh, University of Pittsburgh.

GERSTEN, Samuel, Staten Island, N. Y., Syracuse University.
HANNON, Harland N., Louisville, Ky., Kansas City University.
JONES, Charles W., Baltimore, University of Maryland.
KING, William D. Jr., Miami, Ariz., Baylor University.
LUCAS, Paul W., Baltimore, Duke University.
MacKILLIP, Daniel, Jr., Cambridge, Mass., Tufts College Medical School.
MURPHY, C. Henry, Staten Island, N. Y., Georgetown University.
MYERS, Mark E., Charlottesville, Va., University of Virginia.
RAPPAORT, Eugene O., Staten Island, N. Y., University of Lausanne, Switzerland.
TRAIN, John B., New York, New York University.
VANDERHOOK, Ray H., Buffalo, College of Medical Evangelists.
WHITE, James N., Dallas, Texas, University of Texas.
WOLFE, Roy E., Denver, University of Colorado.

ORGANIZATION SECTION

EXHIBITS FOR MEDICAL SOCIETIES AND SCIENTIFIC ORGANIZATIONS

Exhibits pertaining to the work of the various departments of the American Medical Association and to subjects in which those departments are interested have been prepared for medical societies and other scientific organizations.

The exhibits are available on a loan basis. Responsibility for installation and demonstration of the exhibits ordinarily must be borne by the organization to which the material is lent. Except in special instances, the American Medical Association will be unable to send its own personnel for such duties.

Requests for material should be instituted as far in advance as possible, so that the proper reservations can be made. Exact shipping addresses and dates should be given when the request is made.

Further information may be obtained from
Director, Scientific Exhibit, American Medical Association,
535 North Dearborn Street, Chicago.

13. Medical Discoveries of a Century.

An exhibit, originally shown at A Century of Progress Exposition in Chicago, consisting of nine groups of figures—Beaumont, Morton, Pasteur, Lister, Roentgen, Theobald Smith, Curie, Ehrlich and Banting. Each group is set in a case with indirect lighting. Models are made of plaster and require great care in handling.

Space required, an area 10 feet wide by 6 feet deep (or 16 linear feet); no background necessary.

Electrical connections, nine outlets, each for a 60 watt lamp.
Shipping weight, 672 pounds.

16. Heroes of Medicine.

An exhibit, originally shown at the Golden Gate International Exposition in San Francisco, consisting of ten groups of figures—McDowell, Beaumont, Long, Holmes, Sims, Welch, Gorgas, Theobald Smith, Ricketts and Reed. Each group is set in a case with indirect lighting. Models are made of rubber and are quite substantial.

Space required, area 10 feet wide by 10 feet deep (or 21 linear feet).

Electrical connections, ten outlets using a total of 400 watts.
Shipping weight, 840 pounds.

30. Hospital Service in the United States.

An exhibit from the Council on Medical Education and Hospitals presenting data on hospitals collected in the annual survey; miscellaneous posters and pamphlets.

Space required, one or two booths according to material selected, together with tables for literature.

Shipping weight, according to material selected.

32. Medical Education in the United States.

An exhibit from the Council on Medical Education and Hospitals consisting of charts showing statistics on medical education in the United States, together with miscellaneous maps and literature.

Space required and shipping weight, according to amount of material selected.

34. Tularemia (spread and control).

An exhibit from the Scientific Exhibit of the American Medical Association made in conjunction with Dr. Walter M. Simpson, Miami Valley Hospital, Dayton, Ohio, and Dr. Edward Francis, U. S. Public Health Service, Washington, D. C., consisting of transparencies showing clinical cases of tularemia and posters on panels showing the prevalence, animal

hosts, insect vectors and what to do to prevent infection. An exposition "microscope" shows the tularemia organism.

Space required, an area 10 feet wide by 6 feet deep; no background necessary.

Electrical connections, two outlets for lamps in transparency case and exposition "microscope" using 255 watts.

Shipping weight, 297 pounds.

35. Tularemia (pathology).

An exhibit from the Scientific Exhibit of the American Medical Association of photographs, photomicrographs and roentgenograms collected by Dr. Walter M. Simpson and Dr. Edward Francis, showing the pathologic changes of tularemia in animals and man.

Space required, an area 10 feet wide by 6 feet deep; no background necessary.

Electrical connections, one outlet for lamps in transparency case using 240 watts.

Shipping weight, 260 pounds.

50. Use and Abuse of Barbiturates.

An exhibit from the Council on Pharmacy and Chemistry consisting of posters showing the use and abuse of the barbiturates; a chart giving the names and chemical formulas of thirty products on the market; an exposition file and New and Nonofficial Remedies giving additional information.

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep on which to hang charts and posters; a table for exposition file and N. N. R.

Shipping weight, 103 pounds.

51. Work of the Council on Pharmacy and Chemistry.

An exhibit from the Council on Pharmacy and Chemistry consisting of miscellaneous posters, each 22 by 28 inches, from which selections can be made to fit any space desired.

Shipping weight, from 40 to 50 pounds.

52. Work of the A. M. A. Chemical Laboratory.

An exhibit from the Chemical Laboratory, similar to the one from the Council on Pharmacy and Chemistry, consisting of posters from which selections can be made to fit any space desired.

Shipping weight, from 40 to 50 pounds.

53. Work of the Council on Foods and Nutrition.

An exhibit from the Council on Foods and Nutrition consisting of miscellaneous posters, each 22 by 28 inches, containing the various items of information concerning the work of the Council.

Shipping weight, according to amount of material selected.

54. Work of the Council on Physical Therapy.

An exhibit from the Council on Physical Therapy consisting of miscellaneous charts in frames, each 22 by 28 inches, together with selected apparatus. The following groups have been found of interest: short wave diathermy; simple apparatus for physical therapy; miscellaneous posters dealing with the work of the Council.

Space required, variable according to kind of material selected.

Electrical connections, one or more outlets if mechanical material is selected.

Shipping weight, variable according to material selected.

55. Posture.

An exhibit from the Council on Physical Therapy consisting of a manikin for visitor participation showing correct and incorrect posture; transparencies showing reasons for good

posture and panels with posters showing the relation of sitting and posture, the feet and posture, the causes of poor posture and recommendations for good posture. An exposition file gives additional information.

Space required, an area 10 feet wide by 6 feet deep; no background necessary; two small tables, one for manikin and one for exposition file.

Electrical connections, three outlets for lamps in cases using a total of 440 watts.

Shipping weight, 368 pounds.

61. Medical Economics.

An exhibit from the Bureau of Medical Economics consisting of miscellaneous charts; a rack for literature showing the publications of the Bureau and two exposition files containing various items of information concerning medical economics.

Space required, a booth with back wall 10 feet wide and two side walls each 6 feet deep.

Shipping weight, 240 pounds.

63. Industrial Health.

An exhibit from the Council on Industrial Health consisting of a group of posters showing the status of industrial health in the United States together with an exposition file giving additional information.

Space required, a booth with back wall 10 feet wide and side walls on which to hang posters; table for exposition file.

Shipping weight, 166 pounds.

64. Silicosis and Pneumoconiosis.

An exhibit from the Council on Industrial Health in conjunction with the Saranac Laboratory consisting of transparencies and panels showing the essential facts about benign pneumoconiosis, simple nodular silicosis, simple conglomerate silicosis, tuberculosilicosis and asbestosis.

Space required, an area 30 feet wide by 6 feet deep; no background necessary.

Electrical requirements, five outlets for transparencies, alternating current, 400 watts.

Shipping weight, 991 pounds.

66. Basic Science Laws.

An exhibit from the Bureau of Legal Medicine and Legislation consisting of six charts and frames, each 22 by 28 inches, together with a shadow box.

Space required, a booth with back wall 10 feet wide, and side walls 6 feet deep (15 linear feet).

Electrical connections, one outlet, 120 watts.

Shipping weight, 154 pounds.

67. Medical Legislation and Medicolegal Topics.

An exhibit from the Bureau of Legal Medicine and Legislation consisting of miscellaneous charts in frames, each 22 by 28 inches.

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep (or 15 linear feet).

Shipping weight, 60 pounds.

70. Cutaneous Manifestations of Tuberculosis.

An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of four panels each 5 feet high and 3 feet wide, showing photographs of cutaneous tuberculosis and conditions which simulate it.

Space required, an area 10 feet wide by 3 feet deep; no background necessary.

Shipping weight, 166 pounds.

71. Cutaneous Granulomas.

An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of photographs of various granulomas (other than tuberculosis and syphilis), including one panel of leprosy and one panel of drugs. The photographs are mounted on six panels, each 5 feet high and 3 feet wide, with legs $2\frac{1}{2}$ feet high, which can be installed readily.

Space required, an area 12 feet wide by 3 feet deep; no background necessary.

Shipping weight, 250 pounds.

72. Cutaneous Manifestations of Syphilis.

An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of about 150 photographs of the various syphilitic lesions in different stages of the disease. The photographs are mounted on panels 5 feet high by 3 feet wide, with legs $2\frac{1}{2}$ feet high, which can be installed readily.

Space required, an area 18 feet wide by 3 feet deep; no background necessary.

Shipping weight, 327 pounds.

78. Aesculapius, Hygeia, Hippocrates and Osler.

Four plaster plaques in bas-relief from the Bureau of Exhibits showing Aesculapius, Hygeia, Hippocrates and Osler. Each figure is $8\frac{1}{2}$ feet high, 3 feet wide and 6 inches thick. Because of the fragile nature of the plaques, they will be sent only where they can be suitably installed.

Shipping weight: Aesculapius, 343 pounds; Hygeia, 354 pounds; Hippocrates, 300 pounds, and Osler, 366 pounds.

82. Treatment of Early Syphilis.

An exhibit prepared in conjunction with the United States Public Health Service consisting of ten posters, each 22 by 28 inches, together with an exposition file containing various items of information about the treatment of early syphilis. (A duplicate of this exhibit can be obtained also from the United States Public Health Service, Washington, D. C.)

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep.

Shipping weight, 125 pounds.

84. Treatment of Prenatal Syphilis.

An exhibit prepared in conjunction with the United States Public Health Service, consisting of ten posters, each 22 by 28 inches, together with an exposition file containing various items of information about the treatment of prenatal syphilis. (A duplicate of this exhibit can be obtained also from the United States Public Health Service, Washington, D. C.)

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep.

Shipping weight, 81 pounds.

86. Treatment of Late and Latent Syphilis.

An exhibit prepared in conjunction with the United States Public Health Service, consisting of ten posters, each 22 by 28 inches, together with an exposition file containing various items of information about the treatment of late and latent syphilis. (A duplicate of this exhibit can be obtained also from the United States Public Health Service, Washington, D. C.)

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep.

Shipping weight, 119 pounds.

91. Hygeia in Office, School and Home.

An exhibit prepared in conjunction with *Hygeia*, the Health Magazine, consisting of five dioramas showing the use of *Hygeia* in office, school and home.

Space required, an area 10 feet wide by 3 feet deep; no background necessary.

Electrical connections, five outlets, requiring a total of 300 watts.

Shipping weight, 250 pounds.

95. Anesthesia.

An exhibit from the Scientific Exhibit of the American Medical Association, consisting of charts, transparencies and an exposition file giving information concerning anesthesia.

Space required, a booth with back wall 10 feet wide and side walls 6 feet deep.

Electrical requirements, one outlet using 240 watts.

Shipping weight, 267 pounds.

OFFICIAL NOTES

THIRD ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Arrangements have been completed for the third annual Congress on Industrial Health sponsored by the American Medical Association, which will be held Monday and Tuesday, Jan. 13 and 14, 1941, at the Palmer House in Chicago.

These meetings are open to all physicians and others interested in the industrial health movement. There is no registration fee. Topics and speakers are as follows:

OPENING SESSION, MONDAY, 9:45 A. M.

Report of the Council on Industrial Health.

STANLEY J. SEEGER, M.D., Chairman, Milwaukee.

The Physician in Industry and National Defense.

IRVIN ABELL, M.D., Chairman, Health and Medical Committee in the Council of National Defense, Louisville, Ky.

Current Needs in Industrial Hygiene Research.

PHILIP DRINKER, Professor of Industrial Hygiene, Harvard University, Boston.

The Special Nature of Industrial Practice.

C. O. SAPPINGTON, M.D., Chicago.

Disability Evaluation in Silicosis.

J. L. BLAISDELL, M.D., Porcupine Clinic for Silicosis Research, St. Mary's Hospital, Timmins, Ontario.

Red Lacquer Room

MONDAY, 2 P. M.

HAND INJURIES

Anatomic Diagnosis of Injuries of the Hand.

JAMES M. WINFIELD, M.D., Associate Professor of Surgery, Wayne University College of Medicine, Detroit.

Treatment of Superficial Hand Injuries and Burns.

HARVEY S. ALLEN, M.D., Chicago.

Division of the Nerves and Tendons of the Hand.

MICHAEL MASON, M.D., Chicago.

Importance of Purposeful Splinting Following Injuries of the Hand.

HENRY C. MARBLE, M.D., Boston.

Prevention and Treatment of Hand Infections.

SUMNER L. KOCH, M.D., Chicago.

Red Lacquer Room

MONDAY, 2:30 P. M.

AVAILABILITY OF TRAINED INDUSTRIAL HEALTH PERSONNEL

The Trained Industrial Nurse.

RUTH HOULTON, R.N., Secretary, Industrial Nursing Section, National Organization for Public Health Nursing, New York.

The Industrial Hygiene Engineer.

(Speaker to be announced.)

The Safety Engineer.

W. H. CAMERON, Managing Director, National Safety Council, Inc., Chicago.

The Medical Industrial Hygienist.

PAUL A. NEAL, M.D., Chief of the Division of Industrial Hygiene, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

The Physician in Industry.

ROBERT T. LEGGE, M.D., University of California, Berkeley, Calif.

Room 8

MONDAY, 6:30 P. M.

An informal dinner and round table discussion intended primarily for state and county medical society committees on industrial health will be held. The subject matter for discussion will include problems of organization and plans for future activity.

TUESDAY, 9:30 A. M.

Employment of the Physically Handicapped.

D. L. LYNCH, M.D., President, American Association of Industrial Physicians and Surgeons, Boston.

Aging as a Problem of Industrial Health.

EDWARD J. STIEGLITZ, M.D., Research Associate in Gerontology, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

ACUTE RESPIRATORY DISEASE IN INDUSTRY

Incidence and Costs of Acute Respiratory Disease in Industry.

ANTHONY J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York.

Respiratory Disease and Air Conditioning.

CAREY P. McCORD, M.D., Chairman, Committee on Air Conditioning of the American Medical Association, Detroit.

The Role of the Physician in Industry in the Control of Acute Respiratory Disease.

GEORGE M. PIERSOL, M.D., Philadelphia.

Red Lacquer Room

TUESDAY, 2 P. M.

INDUSTRIAL OPHTHALMOLOGY

Economic Importance of Visual Disability in Industry.

LEONARD GREENBURG, M.D., Chairman, Industrial Advisory Committee of the National Society for the Prevention of Blindness, New York.

Essentials of First Aid and Later Management of Industrial Eye Injuries.

SIDNEY WALKER JR., M.D., Chicago.

Detection and Control of Defective Vision in Industry.

ARTHUR M. CULLER, M.D., Dayton, Ohio.

Protective Equipment for Eyes in Industry.

THOMAS D. ALLEN, M.D., Associate Clinical Professor of Ophthalmology at Rush Medical College, Chicago.

HENRY F. CARMAN, M.D., San Francisco.

Red Lacquer Room

WEDNESDAY, JANUARY 15

On the day following the congress, the Chicago Medical Society will conduct clinics illustrating practical problems in industrial medicine, industrial hygiene and traumatic surgery.

On the same day the Chicago Medical Society will hold a dinner and evening meeting on the relationship of the private practitioner to the industrial health movement. The program will be:

Industrial Health—A Medical Opportunity.

STANLEY J. SEEGER, M.D., Chairman, Council on Industrial Health, American Medical Association, Milwaukee.

Medical Service for the Small Plant.

ANTHONY J. LANZA, M.D., New York.

The Control of Syphilis in Industry.

HAROLD A. VONACHEN, M.D., Peoria, Ill.

Further details regarding clinics and other demonstrations will be provided registrants at the congress, all of whom are invited to participate.

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the annual session at Cleveland on June 3, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the programs, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in THE JOURNAL and monthly in Hygieia, the Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

November 27. Through Hospital Corridors.

December 4. Paging Doctor Drew.

December 11. The Family's First Friend.

WOMAN'S AUXILIARY

Kansas

Members of the Montgomery County Medical Society and their wives met at the country club at Cherryvale, September 29, for a picnic supper. While the doctors enjoyed golf and target shooting the wives enthusiastically decided to become active in auxiliary work. Dr. and Mrs. Charles Miller were guests, and Mrs. Miller, who is councilor of the third district, presented objectives of the auxiliary today. Dr. and Mrs. T. D. Blasdel of Parsons were also guests, and Mrs. Blasdel, president of the auxiliary to the state society, suggested plans for the year. Mrs. H. O. Bullock of Independence was elected president and a meeting date was set at which time other officers will be elected and committees appointed.

Mississippi

The doctors' wives of Monroe County entertained the visiting auxiliary members of the Northeast Mississippi Thirteen Counties' Medical Society, September 10, at the home of Mrs. W. N. Reed. Mrs. Bernard Patrick, the president, introduced the speaker, Dr. Augustus Street, of Vicksburg, president-elect of the Mississippi State Medical Association. Mrs. Augustus Street urged the auxiliary's liberal offering for the Preventorium Fund. Mrs. Stanley Hill, of Corinth, gave a paper on "Animal Experimentation."

Members of the Adams County auxiliary and their husbands were entertained, October 2, at the home of Dr. and Mrs. W. K. Stowers, Natchez. Dr. E. E. Benoist, master of ceremonies, presented Dr. W. H. Anderson, Boonerville, president of the Mississippi State Medical Association, and Mrs. E. C. Parker, Gulfport, president of the woman's auxiliary to the state medical association. Dr. Anderson urged the wives to study ways of helping improve the service their husbands offer, to welcome opportunities of imparting information to the laity and thus strengthen confidence in the profession, and to strive to be the leaders in work related to medicine.

The officers of the state auxiliary met, October 3, with Mrs. Henry Boswell at the preventorium. The group voted \$30 a month to keep two children at the preventorium.

Nebraska

The auxiliary to the Lancaster County Medical Society met, October 7, at the home of Mrs. Floyd Rogers of Lincoln. Prof. O. H. Binson, of Lincoln High School, talked on his experiences as a member of the Educational Policies Commission and the American Youth Commission.

The auxiliary to the Omaha-Douglas Counties Medical Society held a Harvest Home Benefit Dinner, October 9, at the summer residence of Dr. and Mrs. C. C. Tomlinson. Proceeds from the dinner will benefit the projects adopted at the recent Membership Tea; namely, a subscription to *Hygeia* to all 102 of Omaha's public and parochial schools, the Community Chest, the School Free Lunch Fund and the Nebraska Tuberculosis Health Camp.

A joint dinner meeting of the tri-county auxiliary No. 1 and the Tri-County Medical Society was held, September 26, at the St. Francis Hospital in Grand Island. Mrs. Elmer Hansen, Lincoln, spoke on auxiliary problems; Mrs. J. G. Woodin, president of the auxiliary, talked on "A Look Ahead." Mrs. A. D. Brown, Central City, state president, addressed the group.

Oregon

The woman's auxiliary to the Oregon State Medical Society held its fourteenth annual meeting, September 5, at Eugene with seventy members in attendance. Mrs. V. E. Holcombe, president of the woman's auxiliary to the American Medical Association, was guest of honor. Dr. Hans Lisser, clinical professor of medicine at the University of California Medical School, spoke on "Hypothyroidism," with colored motion picture demonstrations.

Officers for the coming year were installed at the closing session: Mrs. Charles Edwin Sears, Portland, president; Mrs. Charles Hunt, Eugene, president-elect; Mrs. Merle Taylor,

Portland, corresponding secretary; Mrs. Laurence Serrurier, Portland, recording secretary, and Mrs. Paul Lind, Portland, treasurer.

Mrs. Holcombe attended the board meeting of the auxiliary to the Multnomah County Medical Society, September 9, and was guest of honor at a luncheon held at the Town Club. Twenty-six members attended. The auxiliary began its fall activities with a meeting, September 23, at the Portland Golf Club, with forty members present. This is a social occasion each year with bridge and visiting after luncheon.

Six volunteers from the auxiliary assisted with the annual open house and tea, October 5, at the Louise Home for Girls, a charitable organization. Members also assisted with the Silver Tea at Doernbecker Hospital for crippled children, September 21. The auxiliary to the Coos-Curry Counties Medical Society reports that at its first meeting in September the members worked on garments for the county poor farm.

Pennsylvania

The auxiliary honored its medical advisers at luncheon and heard an important lecture on "The World to Come" by Maurice Hindus, a journalist. Entertainment comprised a bus trip to Atlantic City for guests, music and talks by prominent speakers.

The annual meeting of the woman's auxiliary to the Medical Society of the State of Pennsylvania met in Philadelphia with more than 400 members in attendance. Mrs. V. E. Holcombe, president of the national auxiliary, was a guest. From the reports of the committees, it was found that during the current auxiliary year over \$5,500 had been contributed to the Benevolence Fund, Pennsylvania's own plan for caring for needy medical men and their families, contributed to by county groups each year. The auxiliary has contributed over \$37,000 to the fund in the past ten years. Pennsylvania, while not holding its place in national *Hygeia* sales, still did considerable work in that field. The state has followed the program of the national auxiliary and has reached over 5,000 in lay groups with public relation programs. The state auxiliary has a balance of over \$1,600 this year after all bills have been met. The history of the work of the state auxiliary in book form being made by the archives chairman is nearly completed. Twenty counties had model exhibits of original design showing their work in their home fields.

The woman's auxiliary to the Philadelphia County Medical Society began the season with the meeting of the state medical society in Philadelphia, followed by a meeting, October 8. Dr. Edward L. Bortz, president, Philadelphia County Medical Society, regards the work of organized medicine as a function of the auxiliary. He offered to provide physicians to report on the affairs of the county and suggested the ways and means by which the auxiliary might be most helpful. The health education chairman, Mrs. M. Fraser Percival, is ready to place speakers from the bureau of the Philadelphia County Medical Society before clubs.

South Carolina

Mrs. Charles P. Corn, president of the auxiliary to the Southern Medical Association, spoke at the September meeting of the auxiliary to the Greenville County Medical Society. She reported that members in Virginia and North Carolina have endowed beds for tuberculous patients in two sanatoriums. They are memorial beds in which members of doctors' families are given preference. In Alabama the auxiliary maintains a student loan fund.

The auxiliary to the Oconee County Medical Society recently purchased for the library of the Oconee County Hospital an aid for doctors who wish to find references in the medical books placed in the library by the Oconee County Medical Society. Guest speaker at the recent meeting was Dr. E. A. Hines, secretary of the South Carolina Medical Association.

The Spartanburg county medical auxiliary met recently, with Mrs. Charles P. Corn of Greenville, president of the Woman's Auxiliary to the Southern Medical Association, as guest speaker. Another guest was Dr. Ruth Frank Pugh of Converse College.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Hugh F. Dormody, Monterey, was recently elected governor of district 106 of the Rotary International. —Dr. Lee A. Stone, Madera, was elected president of the health officers' department of the League of California Cities at a meeting, September 18, in San Diego.

Program for Pertussis Immunization Proposed.—The San Francisco Department of Health is planning to establish an immunization program against pertussis in a baby welfare center located in a section of the city where economic conditions generally prohibit a given family from securing this service from its private physician. After a trial period the program may be extended to other centers operated by the department if conditions show a need for the service and the experience of the trial station justifies its expansion. While no funds are now available in the present fiscal budget, it is hoped that a sufficient amount will be obtained to launch this work. It was pointed out that the cost of the material alone to the department for one pertussis immunization is eight times the cost of the material used for a complete immunization against diphtheria. The change was planned after the present policy of the department with respect to pertussis immunization was reviewed. Before a decision was made, opinions were requested from some pediatricians in the city and professors in this specialty at the medical schools of Stanford and California universities.

FLORIDA

Fraudulent Licenses Appear.—Two licenses recorded with the state board of medical examiners were recently declared fraudulent and are, according to the board, indications that the diploma mill racket is again being revived. One license, recorded by Lyle Park Johnson last April, was purportedly issued by the old Eclectic Board of Medical Examiners in 1919. Until recently Johnson had been practicing as a naturopath. The other license was recorded in Munroe County in September 1939 by Gavilla Lopez and was also an eclectic license purportedly issued in 1919. Lopez had also been practicing as a naturopath in Tampa. Both men possessed diplomas from the Baltimore Eclectic Medical College, the state medical board reported.

ILLINOIS

Society News.—Dr. Harold C. Lueth, Evanston, discussed "Management of Bright's Disease with Special Reference to the Acute Stage" before the Adams County Medical Society in Quincy, October 14. —Dr. George K. Fenn, Chicago, addressed the Madison County Medical Society in Granite City, November 1, on congestive heart failure. —Dr. Walter C. Alvarez, Rochester, Minn., discussed "Functional Gastrointestinal Disorders" before the Peoria Medical Society, November 12. —The Tri-County Medical Society, comprising Warren, Knox and Henry counties, met in Monmouth, November 1, with the following speakers: Drs. Charles E. Galloway, Evanston, on "Diseases of the Cervix and Treatment"; Chauncey C. Maher, "Treatment of Cardiac Edema"; Philip Lewin, "Infantile Paralysis," and Morris Fishbein, Editor of THE JOURNAL, "The Medical Profession Prepares." All are of Chicago. —Dr. Wayne W. Fox, Evanston, addressed the Christian County Medical Society at Taylorville, October 30, on pneumonia. —Dr. Richard S. Weiss, St. Louis, discussed "Precancerous Lesions of the Skin" before the St. Clair County Medical Society in Belleville, November 6. —Dr. Paul A. Campbell, Chicago, discussed "Medical Problems of Combat Aviation" before the La Salle County Medical Society, October 24, at Starved Rock State Park.

Chicago

Winners of Child Research Grant.—The Institute of Medicine of Chicago announces that the Elizabeth McCormick Child Research Grant of \$1,500 for 1940-1941 has been divided among Drs. Mila I. Pierce, Evanston, Clayton J. Lundy and Heyworth N. Sanford for the continuation of the investigations begun under their 1939-1940 grants. Dr. Lundy's sub-

ject is heart sound records in rheumatic heart disease; Dr. Pierce's, leukosis, and Dr. Sanford's, role of qualitative platelet factors in the coagulation of the blood.

Symposium on the Adult Offender.—The Chicago Academy of Criminology and the Chicago Society for Personality Study held a joint meeting, October 30. The theme of the session was "The Adult Offender." The speakers included:

Dr. Marvin Sukov, psychiatrist, division of the criminologist, State of Illinois, Personality Study of the Adult Offender.
Hans Riemer, supervisor of education, Indiana State Penitentiary, Practical Application in a Prison Program.
Samuel Daykin, sociologist, division of pardons and paroles, State of Illinois, Practical Application in Probation, Parole and Social Readjustments.

Harry M. Fisher, judge of Cook County Circuit Court, and Ernst W. Puttkammer, professor of law, University of Chicago, discussed the presentations.

INDIANA

Society News.—Dr. Jay Arthur Myers, Minneapolis, discussed "The Control of Tuberculosis" before the Fort Wayne Medical Society in Fort Wayne, October 15. —The Delaware-Blackford County Medical Society was addressed in Muncie, October 15, by Drs. Joseph C. Silvers and Nila G. K. Covalt, Muncie, on "Organotherapy of Menstrual Irregularities" and "Organotherapy of the Menopause" respectively. —Dr. Daniel L. Sexton, St. Louis, addressed the Gibson County Medical Society in Princeton, October 14, on "Endocrine Treatment in General Practice." —Dr. Eugene L. Bulson, Fort Wayne, discussed "The Symptoms and Diagnosis of Foreign Bodies in the Air and Food Passages" before the Fort Wayne Academy of Medicine and Surgery, November 12. The academy was addressed, November 19, by Dr. Grover C. Penberthy, Detroit, on "The Surgical Management of Appendicitis."

KANSAS

Changes in Health Officers.—Dr. Hugh M. Swaney, Goodland, has been named health officer of Sherman County. Dr. Charles A. Dieter, Harper, has been appointed in charge of Harper County to succeed the late Dr. Clarence E. Ressler, Anthony, and Dr. James N. Hill, Hutchinson, health officer of Reno County.

Society News.—The Shawnee County Medical Society was addressed, November 4, by Dr. Andrew W. McAlester III, Kansas City, Mo., on "Practical Ophthalmic Therapy." —Dr. Henry M. Winans, Dallas, Texas, discussed "Anemia—Diagnosis of Difficult Cases" before the Wyandotte County Medical Society, November 5, in Kansas City. The society was addressed, October 15, by Drs. Albert J. Rettenmaier on "Biliary Stones with Emphasis on the Exploration of the Common Duct" and Harold V. Holter, "Sterility."

MASSACHUSETTS

Petition Supports Contraceptive Advice.—The Committee for the Defense of Medical Rights has issued a statement in support of an initiative petition to amend the Massachusetts laws relating to prevention of pregnancy. The change in the law would allow physicians to provide medical contraceptive information and care to married persons for the protection of life or health. The petition asks the legislature to amend sections 20 and 21 of chapter 272 of the general laws by adding at the end thereof the following:

The provisions of this section and of section twenty which relate to the prevention of pregnancy and the prevention of conception shall not apply to treatment or prescription given to married persons for protection of life or health by or under the direction of physicians registered in accordance with the provisions of Chapter 112; nor to teaching in chartered medical schools; nor to publication or sale of medical treatises or journals.

The statement issued by the Committee for the Defense of Medical Rights reads:

The initiative petition proposed is for a bill to insure to physicians the right to protect the life, health, and reason of married persons when these might be endangered by pregnancy. It is designed to prevent the legal interference with this phase of the practice of medicine, which has only recently resulted from the enforcement of an old Massachusetts statute.

The principle of legal freedom for physicians to provide contraceptive medical care to married persons whose physical or mental condition would suffer by pregnancy or who could be expected to produce only seriously defective individuals, has been approved by the American Medical Association, and by many other medical and religious bodies.

Support of this petition does not imply support of either the methods or philosophy of "birth control." It means only support of the principle of freedom in the licensed teaching and practice of medicine.

The initiative petition is so designed as to protect morality and marital security and to bring under licensed control the present, widespread bootleg traffic in contraceptive information and material, which we deplore.

Physicians who wish to aid in obtaining signatures to the initiative petition may obtain blanks by getting in touch with Somers H. Sturgis, secretary of the Committee for the Defense of Medical Rights, 270 Commonwealth Avenue, Boston.

NEW YORK

Society News.—Willard H. Wright, Ph.D., Washington, D. C., addressed the Buffalo Academy of Medicine, October 30, on "Common Parasitic Infestations in Children." Dr. Jacob Arnold Bargen, Rochester, Minn., addressed the section of surgery, November 6, on "Differentiation Between Various Types of Ulcerative Colitis and Their Management."—Dr. Harry Dan Vickers, Little Falls, addressed the Herkimer County Medical Society, October 8, on "Surgical Aspects of a Major Railroad Accident."—Dr. William P. van Wagenen, Rochester, addressed the Jefferson County Medical Society, October 10, on "Head Injuries."—Clarence Cook Little, Sc.D., Bar Harbor, Maine, and Dr. William P. Healy, New York, addressed the Medical Society of the County of Nassau, Garden City, October 29, on "Recent Advances in Cancer Research" and "Cancer of the Female Pelvis" respectively.

New York City

Second Harvey Lecture.—Dr. Charles H. Best, Toronto, Canada, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine, November 28. Dr. Best's subject will be "Thrombosis and the Action of Heparin."

Lecture by Dr. Corner.—Dr. George W. Corner, director of the department of embryology of the Carnegie Institution of Washington, located in Baltimore, will deliver a lecture at Cornell University Medical College, December 10, under the auspices of the Nu Sigma Nu Fraternity. Dr. Corner's subject will be "The Ovarian Cycle of the Rhesus Monkey."

OHIO

Personal.—Dr. Joseph J. Kotershall, Cleveland, was recently honored at a surprise dinner given by about seventy-five physicians. It was said that the dinner was in appreciation of "the guiding hand he has always offered to youngsters in the profession." The group gave him a watch as a memento.

University News.—The General Education Fund has recently added \$12,700 to the grant previously made to the Brush Foundation, Western Reserve University School of Medicine, Cleveland, for the study of child health and development under the direction of William Walter Greulich, Ph.D., director of the foundation.

Postgraduate Lectures.—The autumn postgraduate series of lectures sponsored by the Mahoning County Medical Society were presented in Youngstown, November 14-15, with Dr. Henry L. Bockus, Philadelphia, as the speaker. His subjects were "Present Clinical Status of Chronic Gastritis," "What Constitutes Adequate Therapy for Chronic Peptic Ulcer," "Practical Application of Recent Advances in Our Knowledge of Liver Functions," "Diagnosis and Management of Chronic Ileitis and Ileocolitis" and "Diagnosis and Management of the Irritable Colon."

PENNSYLVANIA

Postgraduate Assembly.—The Harrisburg Academy of Medicine presented its annual Postgraduate Assembly, November 14, with the following speakers:

Dr. J. C. Wetherall, Syracuse, N. Y., The Nodular Goiter—Its

Dr. J. C. Wetherall, Syracuse, N. Y., The Nodular Goiter—Its

Dr. Chevalier L. Jackson, Philadelphia, Broncho-Esophagology in Relation to General Medicine.

Dr. Temple S. Fay, Philadelphia, Further Observations on Refrigeration in Human Beings.

Philadelphia

Personal.—Dr. Frederick C. Smith has been elected editor of the *Weekly Roster and Medical Digest*, official organ of the Philadelphia County Medical Society, to succeed the late Dr. Samuel Horton Brown.

Joint Orthopedic Meeting.—The section of orthopedic surgery of the New York Academy of Medicine and the orthopedic section of the Philadelphia County Medical Society held a joint meeting at Jefferson Medical College, November 15. The speakers included:

Dr. James R. Martin, A Simplified Apparatus for Use After Surgery for Torticollis.

Dr. Arthur Bruce Gill, Early Changes in Legg-Perthes' Disease and the Cyclic Course It Pursues.

Dr. Oscar V. Batson, The Vertebral Venous System.

Drs. Ernest A. Bray and Henry I. Sigmund, Injection Treatment for Low Back and Sciatic Pain.

Drs. Benjamin Franklin Buzby and Allan D. Wallis, Spine Fusion—A Modified Hibbs Technic.

RHODE ISLAND

Society News.—At a meeting of the Providence Medical Association, October 7, Drs. Halsey DeWolf, chairman of the state board on medical preparedness, and Lloyd C. Wilson, medical director, state selective service board, spoke on medical preparedness. A symposium on tuberculosis was presented by Drs. Philip Batchelder, Joseph Smith, John I. Pinckney, John C. Ham, Providence, and Ubaldo E. Zambarano, Wallum Lake. Dr. Joseph V. Meigs, Boston, spoke, November 4, on "Female Endocrinology."

TENNESSEE

Chattanooga Clinical Congress.—The Chattanooga and Hamilton County Medical Society held its annual clinical congress October 31. The program of clinics was presented at the Newell Sanitarium in the morning and at the Erlanger Hospital in the afternoon. A banquet was held at the Hotel Patten in the evening with Drs. John Shelton Horsley, Richmond, Va., and Seale Harris, Birmingham, Ala., as the speakers on gastrointestinal surgery, including appendicitis, and "Insulin Jitters" respectively.

TEXAS

Appointments to Medical Faculty.—Dr. John J. Lawless, recently assistant professor of anatomy at the University of West Virginia School of Medicine, Morgantown, has been appointed assistant professor of anatomy at the University of Texas School of Medicine, Galveston. Dr. Lawless took a Ph.D. degree from the University of Minnesota in 1934 and an M.D. from Rush Medical College in 1939. He previously held a teaching fellowship at the University of Minnesota and an instructorship at Georgetown University, Washington, D. C. J. K. Kline, Ph.D., formerly research chemist with Merck and Company and the Bell Telephone Laboratories, has been appointed assistant professor in pharmacology, with special assignments in the department of preventive medicine and public health.

Annual Postgraduate Assembly.—The Postgraduate Medical Assembly of South Texas will hold its ninth annual clinical meeting, December 3-5, at the Rice Hotel, Houston. This meeting is a project of the eighth, ninth and tenth councilor districts of the State Medical Association of Texas. The speakers will be:

Dr. Horton R. Casparis, professor of pediatrics, Vanderbilt University School of Medicine, Nashville, Tenn.

Dr. Milton B. Cohen, director of the Asthma, Hay Fever and Allergy Foundation, Cleveland.

Dr. Claude C. Coleman, clinical professor of neurologic surgery, University of Virginia Department of Medicine, Charlottesville, and professor of neurologic surgery, Medical College of Virginia, Richmond.

Dr. James B. Costen, assistant professor of clinical otolaryngology, Washington University School of Medicine, St. Louis.

Dr. David M. Davis, professor of genito-urinary surgery, Jefferson Medical College, Philadelphia.

Dr. Charles C. Dennie, Kansas City, Mo., professor of clinical dermatology, University of Kansas School of Medicine, Kansas City.

Dr. John H. Dunnington, professor of ophthalmology, Columbia University College of Physicians and Surgeons, New York.

Dr. Sanford R. Gifford, professor of ophthalmology, Northwestern University Medical School, Chicago.

Dr. Byrl R. Kirklin, director, division of radiology, Mayo Foundation, Rochester, Minn.

Dr. Earl D. McBride, assistant professor of orthopedic surgery, University of Oklahoma School of Medicine, Oklahoma City.

Dr. Henry K. Mohler, dean and Sutherland M. Prevost professor of therapeutics, Jefferson Medical College, Philadelphia.

Dr. George Morris Piersol, professor of medicine, University of Pennsylvania Graduate School of Medicine, Philadelphia.

Dr. Floyd T. Romberger, Lafayette Home Hospital, Lafayette, Ind.

Dr. Robert A. Ross, associate professor of obstetrics and gynecology, Duke University School of Medicine, Durham, N. C.

Dr. W. Likely Simpson, professor of otology, laryngology and rhinology, University of Tennessee College of Medicine, Memphis.

Dr. Harvey B. Stone, associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore.

Dr. Howard C. Taylor Jr., William Goodell professor of gynecology, University of Pennsylvania School of Medicine, Philadelphia.

WEST VIRGINIA

Personal.—Dr. Maxwell F. Raine, Point Pleasant, district health officer for Mason, Jackson, Putnam and Roane counties, has been appointed health officer of Kanawha County to succeed Dr. Turner E. Cato, who recently went to Florida.

New Officers of Tuberculosis Association.—Dr. Leo H. Mynes, Charleston, was elected president of the West Virginia Tuberculosis and Health Association at the annual meeting in Clarksburg, September 19. Mr. E. P. Wells, field agent for the association, was appointed acting executive secretary to succeed the late George C. Rowell, Charleston, who died September 14.

HAWAII

Outbreak of Influenza.—Under date of October 4, Sr. Surg. Marion F. Haralson, Honolulu, reported to the U. S. Public Health Service an outbreak of influenza in the Territory of Hawaii, principally in Honolulu, with the occurrence of 1,800 cases and two deaths on the Island of Oahu since September 26. On October 13, Dr. Haralson reported a total of 4,298 cases with six deaths. He stated that the disease was of mild type, the cases averaging about three days of acute illness. For the two weeks ended October 19 and 26, respectively, there were 1,532 and 1,585 cases reported with no deaths. For the latter week, 725 cases were reported on the Island of Oahu. Influenza is not reportable in Hawaii except when officially declared to be epidemic, according to *Public Health Reports*.

GENERAL

Conferences on Therapy.—The therapeutic conferences developed at the Cornell University Medical College, New York, and first published as a series of special contributions in *THE JOURNAL* are to be continued during the present year in the *New York State Journal of Medicine*. The first of the new series will be concerned with the management of fever, the second with the treatment of nephritis. Since similar conferences are being developed in various medical schools, it has been suggested that this material now be published in state medical journals.

National Health Library Moves.—The National Health Library, administered by the National Health Council, announces its removal from the R. C. A. Building, Rockefeller Center, to 1790 Broadway, New York. This library now includes 6,000 volumes and 30,000 pamphlets and receives more than 500 medical and public health periodicals from all parts of the world. Although it is intended primarily for the use of the seventeen health organizations making up the council, individuals who are not members of the supporting organizations may have the privilege of using it for a small fee. A weekly index to the magazines is issued, also available to the public for a small annual subscription.

Jacobi Fellowship for Women Physicians.—The Women's Medical Association of New York offers a Mary Putnam Jacobi Fellowship for medical research of \$1,000, available Oct. 1, 1941, open to any woman doctor, either American or foreign, who is a graduate of a reputable medical school. Applications should be filed with the secretary of the committee by March 1, 1941, and must be accompanied by statements by persons other than the candidate as to (1) health, (2) educational qualifications and (3) previous work. The applicant herself should state the problem she proposes to investigate and send her photograph. The recipient will be expected to give full time to the study of her problem and to make a report for publication at the completion of her research. Application blanks may be obtained from the secretary of the committee, Dr. Phebe L. DuBois, 150 East Seventy-Third Street, New York.

Meeting of Radiologists.—The twenty-sixth annual meeting of the Radiological Society of North America will be held at the Hotel Statler, Cleveland, December 2-6. According to a preliminary program, the speakers will include:

- Dr. John R. Carty, New York, Soft Tissue Radiography.
- Drs. Ernst A. Pöhl and Lester W. Paul, Madison, Wis., Mediastinal and Pulmonary Changes in Erythema Nodosum.
- Dr. Max M. Peet, Ann Arbor, Mich., Ventrulography and Diagnosis of Brain Tumors.
- Dr. William S. Altman, Quincy, Mass., Cholangiography, Fractional Method.
- Drs. Walter C. Popp and Charles H. Watkins, Rochester, Minn., Effect of Roentgen Irradiation on Chronic Lymphatic Leukemia.
- Drs. Howard P. Doub, Jean P. Pratt and Horace C. Jones, Detroit, Combined Irradiation and Surgery in the Treatment of Carcinoma of the Pelvic Colon.
- Dr. Maurice D. Sachs, Portland, Ore., Carcinoma of the Male Breast: A Review of 200 Cases.
- Dr. Davis Spangler, Dallas, Texas, Effect of Roentgen Therapy on Closure of the Epiphyses.
- Dr. Ira I. Kaplan, New York, Irradiation Therapy of Brain Tumors.

Chinese Hospital Destroyed by Fire.—The Women's Hospital, connected with West China Union University, Chengtu on the Burma Road, was completely destroyed by fire following a Japanese air raid in August, according to a letter from Dr. Sven H. Liljestrand to the Board of Foreign Missions of the Methodist Episcopal Church. The fire destroyed all the cystoscopic and electrotherapeutic apparatus except one cystoscope that had been lent to another hospital unit, as well as all the medical periodicals. Dr. Liljestrand reported. If any physicians are interested in assisting him with second hand apparatus and used copies of journals, they are

asked to communicate with the Medical Department, Board of Foreign Missions, Methodist Church, 150 Fifth Avenue, New York. Dr. Liljestrand is a native of New York and graduated from Syracuse University College of Medicine in 1915.

Society News.—Dr. William M. Doughty, Cincinnati, was chosen president-elect of the American Roentgen Ray Society at its annual meeting, October 3, and Dr. Merrill C. Sosman, Boston, was installed as president. The next annual session will be held in Cincinnati, October 6-11. —At the recent meeting of the Association of Military Surgeons of the United States, Dr. James A. Mattison, Glendora, Calif., was inducted into the presidency. Col. James M. Phalen, U. S. Army, retired, Army Medical Museum, Washington, D. C., is the secretary. Louisville has been selected as the place for the next annual session. —The American Association of the History of Medicine held its first fall meeting in Cleveland, October 7. Among the speakers were Drs. David A. Tucker Jr., Cincinnati, "Daniel Drake, Pioneer Medical Educator of the Middle West"; Logan Clendening, Kansas City, Mo., "Memorials of Medicine in America" and Louis S. Deitchman, Youngstown, Ohio, "Early Medical Printing."

Census of Medical Manufactures.—According to preliminary returns from the census of manufactures for 1939, the value at the factory of surgical instruments and parts made last year was \$7,160,692. X-ray and therapeutic apparatus and electronic tubes had a factory value of \$17,886,322. Surgical supplies and equipment and orthopedic appliances aggregated \$71,679,980.

Statistics are not yet available on the 1939 output of drugs and medicines. In 1937, the value of drugs and medicines as reported by the manufacturers in that year's census was \$345,918,343.

Within the surgical supplies industry, a seemingly small item like surgical gut strings alone accounted for \$3,673,516 of production. Surgical gauze and dressings totaled \$12,510,508. Absorbent cotton production was valued at \$3,483,467. Non-medicated adhesive plasters had a value of \$5,946,645, while medicated plasters were produced to the extent of \$3,792,159. Bandages amounted to \$3,588,637. Sterilizers had a worth of \$1,153,680. The remainder of the industry's production is accounted for by items like artificial limbs, trusses, arch supports, surgical belts, and the like.

X-ray apparatus for general medical use had a value at the factory last year of \$8,260,750, plus \$2,112,942 for x-ray tubes. Ultraviolet health lamps were valued at \$1,150,221, while the infra-red totaled \$232,445. The value of high-frequency apparatus produced was \$1,324,978. Physical therapy equipment totaled \$1,378,232. Vibrators and other motor-driven devices were worth \$486,713. All other electromedical and electrotherapeutic apparatus, including electrocardiographs, amounted to \$1,212,339.

Production of surgical instruments and parts in 1939 was valued at \$7,160,692, as compared with \$5,830,430 in 1937. Clinical thermometers had a value of \$1,575,069. Of the \$3,831,225 total for laboratory instruments and apparatus, a substantial amount undoubtedly represents equipment for medical use.

There were fifty establishments primarily engaged last year in the manufacture of surgical and medical instruments, as compared with thirty-nine in 1937. They gave employment to 1,626 wage earners, who received a payroll of \$1,978,574. Salaried personnel numbered 319, with earnings of \$1,006,020. For materials, supplies, fuel, purchased electrical energy and contract work they spent \$2,319,720. In total value of products, they show a gain of 6.4 per cent over 1937.

In the classification of surgical supplies manufacturers, there were 360 plants last year against 323 in 1937. Their 8,468 wage earners received \$8,547,630, while salaried personnel numbering 1,967 had earnings of \$4,728,519. The industry paid out for materials, supplies and the like \$40,296,584. The value of its products rose 3 per cent over 1937.

The manufacture of x-ray and therapeutic apparatus in 1939 occupied eighty-four plants, compared with forty-six in 1937. They had 1,959 wage earners and 692 salaried employees, paying out \$2,744,251 in wages and \$1,815,337 in salaries. Cost of materials, supplies and the like was \$5,754,928. Value of their products increased 4.6 per cent over 1937.

CANADA

The Louis Gross Lecture.—Dr. Emanuel Libman, New York, delivered the third annual Louis Gross Memorial Lecture, November 20, at the Montreal Jewish General Hospital under the auspices of the Montreal Clinical Society. Dr. Libman's subject was "Endocarditis and 'Libman-Sachs' Disease'."

Foreign Letters

LONDON

(From a special correspondent)

Oct. 17, 1940.

An Air Raid in Harley Street

This is a quiet night after two unpleasant ones. I am writing to you in bed in my ground floor back room (which I prefer to the basement, where my family sleeps). I can hear the throbbing hum of an occasional German plane overhead and the quick thud-thud of our antiaircraft guns, but only at odd intervals. We in London have settled down to the queer sort of life we are living and have no intention of leaving it, quite why I don't know, for friends out of London are always urging us (and other people) to leave it, but mostly because one feels that if one leaves London the Germans have got us even that amount down, and we're not having that. The night before last was the first night I have actually got out of bed,

Street, and there are 152 houses in the street. We always feel that it might have been us or it might be us tonight, but one gets very fatalistic about it all and the casualties are really infinitesimal as compared with the damage done, and even that, though bad enough, is only a flea bite when you look at London as a whole. The population is as determined as ever not to flinch from the blows the Germans are giving us, and we know that we are now hitting them just as hard. I happened to turn the radio tonight by accident to the Bremer station, when the announcer we call "Lord Haw-Haw" (from his affected voice) was talking: his description of the last raid on London I knew from personal observation was perfect nonsense; why he had to exaggerate so ludicrously I can't understand for, of course, they have done some damage quite worth describing from his point of view; apparently he prefers absurd lies to the quite horrid enough truth, as a matter of policy.

I was in a tube (subway) yesterday for the first time for a long time and was much interested to see the quiet underground life that has sprung up among a large section of our population—a life with customs and laws of its own. I was there about 3:30 p. m. and already along the walls, in the subway stations, blankets, suitcases, folding chairs or pillows had been laid down in an orderly manner to reserve places. A few youngsters and old people were already in their places, prepared to stay there until the next morning, about 7 o'clock. Surface shelters have been provided pretty freely in all streets, but thousands of people prefer the comparative discomfort but warmth, light and freedom from noises of gun fire and bombs and the feeling of perfect safety deep down in the passages, stairways and station platforms of our underground railway. The government discouraged it and tried to make rules about it, but the population took matters into their own hands and made their own unwritten but strictly obeyed rules for this sort of thing.

Otherwise things go on as before. My telephone has been off (cables damaged by bombs) for a week, but water, gas and electricity are all right. No signs of shortage of food or any real essentials.

Should There Be Nurse-Anesthetists?

The Association of Anesthetists has addressed to the chairman of the board of governors of Addenbrooke's Hospital, Cambridge, a letter of protest, signed by the members of the council, who are leading anesthetists, protesting against an advertisement for a nurse to be trained to act as an anesthetist in the hospital. The letter is the result of a meeting of the council specially convened to consider the matter. The council expressed grave misgiving at the advertisement and stated that it has been unable to trace any effort by the hospital to secure applications of qualified persons for the appointment. The institution of a nurse-anesthetist at a hospital of the standing of Addenbrooke's appears to the council to be a retrograde step which is injurious to the public welfare. It holds that the responsibility for a patient under an anesthetic cannot be safely entrusted to any one who is not medically qualified. As far as the anesthetic is concerned, the anesthetist has to bear the full responsibility, as has been frequently proved in the coroner's court. These duties cannot properly be assigned to an unqualified person. If they were and an accident befel the patient, public resentment would be aroused against the hospital concerned. The Royal Colleges of Physicians and Surgeons have recognized the specialty of anesthetics by granting a diploma. This advance has been due to the labors of medical men who devoted themselves to the study of anesthetics. Further progress can be achieved only by the encouragement of similar efforts. The

Harley Street in the battle of London. Three houses destroyed, the middle one that of Mr. Sampson Handley, the well known surgeon and authority on cancer. The snapshot shows how little the rest of Harley Street has been affected.

dressed fully, had my (already packed) suitcase handy and told the others downstairs to get their clothes on and prepare to leave the house at a minute's notice: we didn't actually have to, but from my window I could see a house only two away from us (round the corner) blazing away after an incendiary bomb, and another house about four or five the other side has had its back bombed and partly demolished. I thought the flames might reach us but they didn't, for our fire services are very efficient indeed and soon got it under control. I hope the censor allows the snapshot I have enclosed to pass: I took it a week or so ago from my front door and it shows what a bomb did that fell opposite: three houses in dust, like teeth pulled out, and several others badly damaged. You can see from the photograph that that is all the damage (so far) in Harley

council points out that in Canada, where the nurse-anesthetist was common, she has now been made illegal and that in the United States her existence is deplored by many of the best authorities. For England, which has in many ways been foremost in the advance of anesthetics, to take a backward step by encouraging unqualified anesthetists would be lamentable.

The staff of Addenbrooke's Hospital replied suggesting that "the grave misgiving" of the committee may be mitigated by the following facts: With the outbreak of war, five of the eight anesthetists of the hospital were mobilized, while the beds have been increased by more than 140 and another 150 are in contemplation. Some inexperienced anesthetists have had to be employed. At the present moment the training of students in administering anesthetics at the London hospitals cannot be ideal, and it is from these that resident anesthetists are drawn. The staff therefore considered the training of its own anesthetists. Some of them had considerable experience as sister-anesthetists in the United States and on the European continent, and a large hospital in England has employed them for years with entire success. To safeguard the interests of surgeon and patient it was decided that each sister-anesthetist should receive six months' training—double that required for a physician.

Butter Ration Reduced

At this season arrivals of butter from Australia and New Zealand are always at their lowest, rising from November with the advance of the summer months in the Southern Hemisphere. Normally this seasonal decline is made good by imports from Denmark and Holland, which are not now available. The minister of food has therefore decided as a precautionary measure to conserve stocks by reducing the butter ration from 4 to 2 ounces a week. But the present fat ration, which includes butter, margarine and cooking fats, will remain at 8 ounces. Thus the diminished butter ration can be compensated by increase of the other fats. As the margarine is vitaminized it is a complete substitute for butter. Another offset is that the meat ration (which is measured by expenditure) is increased from 44 to 50 cents a week. In a broadcast the minister of food has said "In this second year of the war you will have enough to eat, but I shall have to ask you to be prepared for changes for short periods."

ITALY

(From Our Regular Correspondent)

Sept. 15, 1940.

Hospitals in Albania

A project for the enlargement of hospitals functioning in Albania and for the construction of new hospitals with state funds was approved. New pavilions similar to those constructed in the Tyrana hospital will be built in the hospitals of Scutari, Koritza and Valona. In the Scutari hospital the enlargement of the hospital will begin immediately. X-ray equipment is already being established in the Scutari, Koritza and Valona hospitals. The Durazzo hospital will be enlarged to three times its capacity. Other plans for constructing a new hospital in Argirocastro and small hospitals in Kukes and Pesh Kopija and, later on, in Perat and Elbassan are being studied.

Prevention of Measles

Professor Petraghani, general director of public health, recently presented a report on the results of administering a phenolated placental extract which is used in the prevention of measles and known in Italy by the name of "Fenepla." In the Cosenza province the preparation was administered to sixty-seven children who had never had measles but who were exposed to the disease. It developed in six cases. Of seventy-four exposed children in the Reggio Emilia province who were vaccinated with the preparation against measles it developed in none. The author found the preparation valuable in preventing measles especially in schools, colleges and resorts for children.

Congress of Dermatology and Syphilology

At the recent meeting of the thirty-second National Congress of the Società Italiana di Dermatologia e Sifilografia in Bologna Prof. Leonardo Martinotti presided. The first official topic was "Subacute Inguinal Lymphogranuloma." Professor Cerutti reviewed the literature on experimental transmission of the infection. Granular corpuscles exist in the tissues in all cases; whether they represent the true virus of the infection has not been proved. Professor De Giorgio discussed the preparation of antigens for Frei's intradermal reaction. Professor Midana discussed extraglandular forms of the infection.

The second official topic was "Cutaneous Tuberculosis." Professors Bergamasco and Cibiriani reviewed the statistics for Italy, by which they showed that the disease had diminished during the last ten years. Professor Pinetti reviewed the literature on the various forms of tuberculous ultravirus, which, according to him, is not the pathogenic factor of cutaneous tuberculosis: Professor Scolari spoke on the evolution of tuberculin allergy and the desensitizing factors. Professor Lisi discussed experimental cutaneous tuberculosis. Professor Klarer discussed the relations between allergy and immunity in the production of organic reactions of defense and the type of reactions connected with cutaneous tuberculosis. Professor Bertoncini spoke on lupus vulgaris. Professor Versari spoke on the treatment of cutaneous tuberculosis with special reference to climate, heliotherapy, proper diet, local chemical therapy, and local and plastic surgery. The election of president for the society resulted in the reelection of Prof. L. Martinotti.

Deaths

Senator Giuseppe Tusini, professor emeritus of the surgical clinic at Genoa University, is dead. He published books and articles, some of which were "Echinococcosis of the Liver," "Varieties of Endothelia," "Actinomycosis of the Foot," "Chronic Polyadenopathy in Relation to Glanders in Pathogenesis," "Lymphatic Varicocele from Filariasis" and "Cysts and in Tumors of the Pancreas." He was the originator and founder of the Castrensian University during the war of 1914-1918. It was established near the front for students of medicine and surgery who were at the front and who attended the university during rest periods in winter.

Marriages

CHARLES BRUCE KERN, Lafayette, Ind., to Mrs. J. Cooper Props of Muncie, at Harrodsburg, Ky., October 4.

JOSEPH GORDON, Ray Brook, N. Y., to Miss Beatrice Brecker of Brooklyn at Plattsburg, N. Y., October 26.

RUSSELL K. HORSMAN, Kokomo, Ind., to Miss Lotte Nevella Benedick at Manhattan, Kan., September 28.

WILBUR GEORGE DOWNS, Saranac Lake, N. Y., to Miss Helen Hartley Geer of New York, September 14.

WILLARD A. PRICE, Nappanee, Ind., to Miss Nellie R. Coppes of Denver, at Crete, Neb., in September.

LAWSON J. CLARK, Indianapolis, to Miss Mildred Harting of North Manchester, Ind., October 11.

CLARENCE C. BOSSELMANN to Miss Clementine Foster, both of Fort Wayne, Ind., October 5.

LYMAN D. EATON to Miss Alberta Marie Speicher, both of Indianapolis, October 12.

MILTON A. SPITZ, St. Louis, to Miss Lucille Lesch of Madison, Wis., October 6.

IVAN CARLYLE, Sedalia, Ind., to Mrs. May Kingery of Middlefork, October 9.

FAY F. BOYS to Miss Jean Sopko, both of East Chicago, Ind., September 28.

JOHN D. COLLINS to Miss Mary Johnston, both of Seattle, in August.

Deaths

William Lawrence Estes ☉ Bethlehem, Pa.; University of Virginia Department of Medicine, Charlottesville, 1877; University of the City of New York Medical Department, 1878; member of the House of Delegates of the American Medical Association in 1909; member of the American Surgical Association; lectured on physiology and hygiene at Lehigh University from 1883 to 1923; fellow of the American College of Surgeons; served in various capacities on the staff of St. Luke's Hospital; in 1934 received the honorary degree of doctor of science from Lehigh University; aged 84; died, October 20, of coronary sclerosis with occlusion.

Nathaniel Hawley Brush ☉ Santa Barbara, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1914; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease; past president of the Santa Barbara County Medical Society; served during the World War; instructor of psychiatry at his alma mater from 1916 to 1918; on the staff of the Santa Barbara Cottage Hospital and the Santa Barbara General Hospital; aged 53; died, October 21, of carcinoma of the pancreas and biliary obstruction.

Henry Wellington Yates ☉ Detroit; Detroit College of Medicine, 1894; emeritus professor of gynecology and obstetrics at his alma mater, now known as the Wayne University College of Medicine; fellow of the American College of Surgeons; past president of the Wayne County Medical Society and for many years chairman of the cancer committee; gynecologist, Providence and William Booth Memorial hospitals; consultant in gynecology, Woman's Hospital; formerly member of the city plan commission; aged 73; died, October 13, in the Harper Hospital of bronchiectasis and arteriosclerosis.

Joseph A. Estopinal, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1899; member of the Louisiana State Medical Society; at one time secretary of the state board of health; served during the World War; formerly medical inspector of public schools in St. Bernard Parish; at one time professor of laryngology and rhinology, New Orleans Post-Graduate School of Medicine; on the staff of the Illinois Central Hospital; formerly on the staff of the Eye, Ear, Nose and Throat Hospital and the Charity Hospital; aged 64; died, October 9.

Henry Carlton Courten ☉ Richmond Hill, N. Y.; University and Bellevue Hospital Medical College, New York, 1909; fellow of the American College of Surgeons; attending orthopedist to the Jamaica, Queensboro, Lutheran and Mary Immaculate hospitals, Jamaica; visiting orthopedist to the Queen's General Hospital, Jamaica; consulting orthopedic surgeon, Rockaway Beach (N. Y.) Hospital, Evangelical Deaconess Hospital, Brooklyn, and the Flushing (N. Y.) Hospital; past president of the Medical Society of the County of Queens; aged 61; died, October 15.

John P. Munroe, Charlotte, N. C.; University of Virginia Department of Medicine, Charlottesville, 1885; member of the Medical Society of the State of North Carolina; member of the House of Delegates of the American Medical Association in 1915; fellow of the American College of Physicians; past president of the Mecklenburg County Medical Society; formerly professor of neurology and practice of medicine, North Carolina Medical College; president and member of the staff of the New Charlotte Sanatorium; aged 83; died, October 14, of pneumonia.

Torr Wagner Harmer ☉ Boston; Harvard Medical School, Boston, 1907; member of the American Association for the Surgery of Trauma and the New England Surgical Society; fellow of the American College of Surgeons; instructor in anatomy and assistant in surgery at his alma mater; consulting surgeon at the Massachusetts Eye and Ear Infirmary and at the Somerville, Winchester, Symmes Arlington and Waltham hospitals; aged 59; died, October 2, of carcinoma.

Roy Jones Holmes ☉ Miami, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; past president of the Dade County Medical Society; member of the American Urological Association; fellow of the American College of Surgeons; chief surgeon, urologic division, James M. Jackson Memorial Hospital; visiting urologist, Victoria and Dade County hospitals; aged 46; died, October 9, of acute coronary thrombosis.

Francisco Jose Hernandez ☉ San Juan, P. R.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; professor of clinical pathology at the School of Tropical Medicine of the University of Puerto Rico, under the auspices of Columbia University; on the staff of the Sanatorio de la Sociedad Española de Auxilio Mutuo y Beneficencia, Rio Piedras; aged 58; died, October 4, of heart disease.

Ovid Clemmons Foote ☉ Surgeon Lieutenant Commander, United States Navy, retired, Washington, D. C.; Johns Hopkins University School of Medicine, Baltimore, 1912; member of the American Urological Association; entered the navy in 1914; served during the World War; retired in 1924 for incapacity resulting from an incident of service; aged 53; died in October of injuries received in an automobile accident.

Guy Hunt Cochran ☉ Los Angeles; Columbia University College of Physicians and Surgeons, New York, 1900; member of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; aged 67; chief of staff of Children's Hospital from 1915 to 1937; for many years on the attending staff of the Hospital of the Good Samaritan, where he died, October 7, of carcinoma of the bronchus.

Walter William Propst ☉ Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1916; past president of the Lackawanna County Medical Society; served during the World War; at various times on the staff of the West Side, Scranton State and Mercy hospitals, Scranton, and the Mid-Valley Hospital, Peckville; aged 55; died, October 11, of pneumonia.

Nicholas Francis Brecker, Philadelphia; Medico-Chirurgical College of Philadelphia, 1907; member of the Medical Society of the State of Pennsylvania; on the staffs of the Presbyterian and the Philadelphia General Hospital; aged 58; died, October 11, of acute coronary occlusion.

Lewis Gordon Allbritton, Birmingham, Ala.; Indiana University School of Medicine, Indianapolis, 1928; member of the Medical Association of the State of Alabama; aged 40; died, October 4, in the Johns Hopkins Hospital, Baltimore, of glioma and spongioblastoma multiforme.

Alexander Donald Ferguson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; served during the World War; aged 54; died, October 14, of injuries received when he was struck by an automobile.

Jesse Ira Whittenberg, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1894; formerly county coroner and health officer; served with the United States Public Health Service during the World War; aged 68; died, September 24, of carcinoma of the throat.

Adelbert Boyd Miller ☉ Erie, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1905; past president of the Erie County Medical Society; served during the World War; aged 59; president of the staff of the Hamot Hospital, where he died, September 11.

Rudolph Clarence Pfeil ☉ Milwaukee; Milwaukee Medical College, 1908; served during the World War; on the staffs of the Johnston Emergency Hospital and St. Luke's Hospital; aged 57; died, October 3, of carcinoma of the pancreas.

George Washington Anglin, Warsaw, Ind.; Northwestern University Medical School, Chicago, 1905; member of the Indiana State Medical Association; served during the World War; aged 66; was drowned, September 15.

Morris Bander, New York; University and Bellevue Hospital Medical College, New York, 1925; physician in the men's hygiene department, Brooklyn College; aged 39; died, October 22, of coronary thrombosis.

Frederick Da Costa Austin, Charlotte, N. C.; North Carolina Medical College, Charlotte, 1907; county coroner; aged 54; died, October 14, in the Mercy Hospital of cerebral hemorrhage and chronic nephritis.

Walter R. Coryell, St. Louis; American Medical College, St. Louis, 1878; aged 86; died, October 10, in the Alexian Brothers Hospital of injuries received in a fall.

Rene Plamondon, Quebec, Que., Canada; Laval University Faculty of Medicine, Quebec, 1906; aged 56; died, August 21.

Correction.—Since publication of a statement concerning the relationship of Dr. John T. Hodgen, former President of the American Medical Association, and the late Dr. William Allen Pusey, in THE JOURNAL, October 12, further correspondence from relatives and friends shows that Dr. Hodgen was a second cousin to Dr. Pusey.

Correspondence

MEDICAL CONTROL OF MOBILIZATION

To the Editor:—In an editorial entitled "The Medical Control of Mobilization" in *THE JOURNAL*, October 12, it is stated that "Much control over the epidemic intestinal diseases such as typhoid and dysentery can be exerted by suitable preventive measures, but the situation with regard to respiratory diseases is more difficult. In such conditions as measles and mumps neither prevention nor treatment can be much better controlled than formerly."

I am under the impression that the use of immune globulin and convalescent serum in measles and of convalescent serum in mumps has become firmly established as of great value in the prophylaxis of these diseases. Certainly in hospital practice we no longer have the terror of measles running through our wards at will as it used to do, and it would seem to me that by establishing depots of suitable convalescent serum the same situation would hold in army camps.

By inoculating all the susceptible in the same building one surely should cut down the spread of these diseases to a minimum.

Of course large amounts of convalescent or immune serum would be necessary, but we all know of centers in New York and elsewhere where such is already the case. It would seem that establishing such facilities should be one of the important adjuncts of mobilization.

CHARLES F. WALCOTT, M.D., Cambridge, Mass.

CLOSED METHOD OF TREATING COMPOUND FRACTURES

To the Editor:—The editorial (*THE JOURNAL*, September 21) devoted to the "Closed Method of Treating Compound Fractures and Infected Wounds" stirs me to add a few words to the discussion. These words have been repeated many times during the past fifteen years, becoming somewhat of a habit, harmless but perhaps boring. They run as follows:

The elements of this method were erected into a doctrine sometime before 1885 by Leopold Ollier of Lyons. He called it simply "delayed dressings" and then elaborated on the technic in much the same terms that are employed today, plaster, odor and all. Some of the credit for his ideas he assigned to Langenbeck and to Poncet. Since then his doctrine has been quite faithfully followed by the Lyoneses, in theory and in practice. Mention in the literature is rare because the ideas involved are taken for granted by the heritors of the Ollier tradition. Besides, the aloof, dour old town, birthplace of Emperor Claude, a "free city" for ages, home of Rabelais and Dolet, haven of Calvin and Servetus, disdains advertising anyhow. But a special application of the method to the treatment of compound fractures with delayed union was advanced by Louis Tixier in 1917, both in the literature and before groups of American surgeons, and it was also discussed by Jean Haour in a thesis about 1925.

As a consequence of the foregoing, I once again urge that the method be associated with the name of Ollier. Any one familiar with the monumental "Traité des resections" or with the surgical practices of the Lyons school will agree that in this way the memory of the "distinguished surgeon of Lyons" (Senn) will be justly honored. Moreover, the method will receive a convenient appellation. Ollier's own term is inadequate and the one used by *THE JOURNAL* is cumbersome. Therefore let it be "Ollier's Method."

ALBERT DE GROAT, M.D., Detroit.

CHRONIC NEPHRITIS AND LEAD POISONING

To the Editor:—I have read with interest your leading article in *THE JOURNAL* of May 4 on my book on "Chronic Nephritis and Lead Poisoning." This book was published seven years ago, and since that date the Queensland government has brought in stringent legislation against the use of lead paint in places accessible to children. This action was taken after my observations had been fully investigated. Much more confirmatory work has been carried out by Dr. Gilbert Murray and his co-workers of the Commonwealth Health Department and by Dr. E. H. Derrick of the Queensland Health Department.

Owing to the new legislation these cases will soon become a rarity, and it is tragic that such splendid research material is being entirely neglected because, owing to war activities here, no one is able to devote time to the further investigation of this very important question, which will almost certainly throw new light on the etiology of many cases of arteriosclerosis.

If an American research organization could send out a skilled researcher I feel sure that in two years he would be able to collect sufficient evidence to write a new chapter on vascular sclerosis. Those of us who have studied this question in Queensland can state dogmatically that in this climate chronic lead poisoning in childhood, when sufficiently severe to cause paralysis, is almost invariably followed by arteriosclerosis and chronic nephritis in early adult life. Most of Queensland is situated within the tropics, and it is my belief that the heat factor plays some part in this morbid process.

You can be assured that herein is a remarkable opportunity for research for which very little funds would be needed.

As the cases are fast disappearing I feel that it would be most unfortunate if this exceptional opportunity were neglected. Can you help?

L. J. JARVIS NYE, M.B., CH.M., F.R.C.P.,
Queensland, Australia.

"ELECTRICAL CONVULSION TREATMENT OF MENTAL DISORDERS"

To the Editor:—In the editorial in *THE JOURNAL*, August 10, on "Electrical Convulsion Treatment of Mental Disorders," credit was accorded to Cerletti for first utilizing the electric current in 1937 to induce epileptic seizures in animals. I should like to call attention to a paper by Clark and Wall (Unconsciousness Produced by Electric Currents, *Quart. J. Exper. Physiol.* 24:85 [Feb.] 1934) which states that in 1900 Leduc, by applying certain types of current to an animal's head, produced a fit with loss of consciousness varying in degree from a condition resembling sleep to one of deep coma and loss of reflexes but without causing any permanent damage to the animal.

Robinovitch (Sommeil électrique, Nantes, 1906) also described a condition in animals which she called "épilepsie électrique" and in which loss of consciousness was associated with many features characteristic of the epileptic fit. Weiss (*Bull. Soc. Internat. des Elect.*, Paris 1:417:1911) and Hess (*Compt. rend. Soc. de biol.* 107:1333 [Aug. 5] 1931) confirmed these results.

Clark and Wall showed that (1) animals displayed no fear of repeated shocks and seemed quieter and more docile for a considerable time after treatment; (2) an initial fall in blood pressure occurred which was abolished by section of the vagi; (3) by direct observation through a window in the skull the cerebral vessels were constricted, followed by dilatation after the current was switched off, and (4) direct cerebral stimulation and not vasoconstriction of the cerebral vessels was responsible for the convulsions, since stimulation of the proximal

end of the cervical sympathetics, while producing vasoconstriction, did not elicit an epileptiform seizure.

I trust that these references will add to the experimental background of the electroconvulsive therapy.

WILLIAM FURST, M.D., Philadelphia.
Philadelphia General Hospital.

USE AND ABUSE OF ADVERTISING BROCHURES

To the Editor:—Your editorial in *THE JOURNAL*, October 5, entitled "Use and Abuse of Advertising Brochures" calls attention to a condition which results in serious economic waste, waste of the recipient's time in inspecting and disposing of unwanted brochures, waste in material and postage on the part of the sender, and waste in the way of an unnecessary tax on the postal facilities of the government.

Besides the example noted in your editorial of the doctor who had received over 300 pounds of such matter in about a year's time, I recall an example in which during an absence of two months there came to a doctor's office 16½ pounds, or 222 pieces, of such material, of which not more than 5 per cent was of any possible interest to him.

This wasteful condition will be remedied if recipients will (1) Write "Refused" or "Not accepted" above address, (2) draw a line through but leave legible the name and address and (3) remail.

The brochure will then be returned to the sender, who will pay the return postage and will or should revise his mailing list.

W. E. CARSON, M.D., Pittsburgh.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

NEPHROSIS OR NEPHRITIS

To the Editor:—What diet and medication can be suggested for an 18 year old youth with considerable swelling of the face, rales throughout the lung fields, swelling of the ankles and possibly slight fluid accumulation in the abdomen? The heart sounds are of normal quality, rate and rhythm; there is normal temperature; the blood pressure is 160 systolic, 110 diastolic; the specific gravity of the urine is 1.010 and the urine is almost solid with albumin. There are no casts, blood or pus. The urea nitrogen is 20.2 mg., urea clearance 63 per cent, hemoglobin 52 per cent, red cells number 2,980,000, white cells 6,800. There is a normal differential count. The tonsils were removed years ago and there appears to be no other source of infection. Is this more of a nephrosis than nephritis? Would it be advisable to give salyrgan? M.D., New Jersey.

ANSWER.—Whether or not a condition of pure nephrosis or a nephrotic syndrome of Bright's disease or both exists is at present the subject of much discussion. Nevertheless the nephrotic picture in its purer forms is definitely an entity, and its diagnosis and treatment differ from that of nephritis. In addition to the features mentioned in the query there are constantly present in nephrosis elevation of blood cholesterol to levels frequently above 300 mg. (this being the only increase in blood chemistry) and a definite lowering of plasma protein, the albumin fraction to a greater degree than globulin, resulting in a reversal of the albumin:globulin ratio. Blood pressure is usually within normal limits and elevation of the degree noted indicates vasoconstriction, which may result in renal ischemia with ultimate insufficiency and a clinical picture more of the uremic type.

However, the process rarely reaches this stage, since recovery takes place or death occurs from intercurrent infection. A great point of difference between nephritis and so-called pure nephrosis is that patients with the latter succumb to a pure nephrosic infection, commonly pneumococcal peritonitis; in fact, some writers state that they have observed only this cause

of death in such cases. Among the commonest causes of onset or recurrence is chilling. The diagnosis in this case would probably be nephrosis. When tubular damage exists, the use of mercurial diuretics such as salyrgan is not advised. The xanthine derivatives, especially theophylline and theobromine and their derivatives may be used (Marvin, H. M.: *Therapy of Dropsy*, *THE JOURNAL*, March 2, 1940, p. 757). More important is the fact that the edema is due to decrease of osmotic pressure of the blood resulting from loss of plasma protein. A common fault in treatment is inadequate protein in the diet. This may be administered in any form, but meat should furnish a large portion of the protein. Quantitatively, three needs must be fulfilled: (1) the daily requirement which by liberal calculation may be 1 Gm. per kilogram of dry weight, (2) renal loss, often from 20 to 30 Gm. daily, and (3) reserve for building up the depleted plasma proteins. This amount is arbitrary and may be increased until the total approximates the patient's tolerance. It should be borne in mind that a gram of meat, for example, does not represent a gram of protein.

Absolute restriction of sodium is necessary in nephrosis. This means no salt, sodium bicarbonate or alkaline preparations. The dietary management is most difficult since a daily diet containing 3 Gm. or less of salt is almost a problem for quantitative diet experts. Butter must be unsalted, no milk is permitted and bread must be specially prepared without salt, in addition to avoiding all salting of other food and avoiding salt-containing food, potato chips and the like. Potassium chloride 3 Gm. given daily to be used as salt on food or in 0.5 Gm. coated tablets may be used. There is no need for undue fluid restriction, as edema is influenced by factors other than water intake. Other than this, rest, warmth and other general measures may be indicated.

ONE HOUR-TWO DOSE DEXTROSE TOLERANCE TEST

To the Editor:—What is the significance of the sugar tolerance test which is completed in one hour by the following method: 1. Collect specimen of urine and blood and administer 50 Gm. of dextrose. 2. In one half hour repeat. 3. In another half hour collect a third specimen of blood and urine. How can this test prove or disprove a diabetic blood sugar curve, when the essential diagnostic point is the return of the blood sugar to normal in two to three hours in the nondiabetic and the lack of return in the diabetic? Kindly discuss, especially in its application to the diagnosis of renal glycosuria. M.D., Ohio.

ANSWER.—The test described is the one hour-two dose procedure devised by Exton and Rose. It is based on the well known Hamman-Hirschman (Staub-Traugott) effect: the administration of dextrose to a normal individual sets in motion certain processes (probably in the liver and pancreas) which make it easier for the body to utilize a second amount of dextrose given a short time later so that the peak of a second blood sugar curve is lower than that of the first; in a diabetic individual, however, the second dose gives rise to still more pronounced hyperglycemia.

Exton and Rose outlined criteria of diagnosis which depend chiefly on the height and extent of the blood sugar curve during the second half hour as opposed to that during the first. These criteria have been analyzed by Matthews, Magath and Berkson, who reported recently on results with the Exton-Rose test in a series of 117 normal persons and 304 individuals diagnosed clinically as diabetic. They conclude that the most reliable figure obtained is the hour value for the blood sugar and suggest that the half-hour value be dispensed with. They regard 158 mg. per hundred cubic centimeters for the hour value as a critical level; individuals with a reading below this point are regarded as nondiabetic and those with values at or above this value are designated as presumptively diabetic. The diagnosis of diabetes is thought definite if the hour value is 180 mg. or above.

These conclusions make one wonder whether it is profitable to divide the 100 Gm. of dextrose into two doses as advised by Exton and Rose, since the revised procedure suggested by Matthews and his co-workers returns closely to that of the standard dextrose tolerance test. These workers suggest two possible advantages of the divided dose even though only the fasting and the hour values are obtained: dividing the dose avoids the necessity of taking an unpleasantly large amount of sugar at one time and possibly brings out more clearly the divergence of the diabetic from the normal response.

The only significant difference between the response of the individual with renal glycosuria and that of the normal person is that the former will exhibit glycosuria throughout the test or at least after the administration of dextrose.

It must be borne in mind that, in the Exton-Rose test as well as in the standard sugar tolerance test, interpretation of the results will vary depending on whether venous or capillary blood samples are taken; capillary values will, in the normal person, be from 10 to 50 mg. higher after dextrose than the corresponding venous figures. Furthermore any of the conditions, such as previous restriction of carbohydrate, previous administration of insulin or infections, will influence the Exton-Rose just as they will the standard sugar tolerance test.

EXTRAGENITAL SERONEGATIVE PRIMARY SYPHILIS

To the Editor:—A chancre of the finger, diagnosed by finding spirochetes seventeen days after the lesion first appeared, healed rapidly after treatment started. Blood tests were negative. 1. If the patient remains seronegative and without further symptoms or signs and continues treatment, what is the likelihood of transmitting the disease and by what manner and for how long a period after the initial lesion has healed? 2. What would you consider adequate treatment? 3. What do surgeons usually do about continuing work? M.D., Republic of Panama.

ANSWER.—1. If this patient with extragenital seronegative primary syphilis remains seronegative as to blood spinal fluid during one year of continuous antisyphilitic treatment, the risk of transmitting the infection to others from any ordinary daily contact is practically nil. For the complete protection of others, sexual intercourse should be completely avoided for the first six months of treatment; during the second six months it may be resumed with condom protection during the arsenical phases of therapy only; during the ensuing year of probation, it may be permitted with condom protection. Unrestricted sexual intercourse should not be permitted until completion of one year of post-treatment probation. Moist kissing should also be avoided for the year of treatment and the year of probation.

2. Adequate treatment consists of courses of an arsphenamine alternating with courses of a bismuth compound by the continuous system, no rest period being permitted, carried out during a full year of seronegativity of the blood. The system, drugs and dosage should be those suggested by the Cooperative Clinical Group.

3. There is no objection to a surgeon continuing work, though of course he should always wear rubber gloves during any surgical procedure, no matter how minor.

MORPHINE AND PROSTIGMINE IN PERITONITIS

To the Editor:—Would you explain the effects of prostigmine and morphine in peritonitis. M.D., New Jersey.

ANSWER.—Morphine and prostigmine are of value in ileus in that they both increase the intestinal tone. In peritonitis, prostigmine preferably should not be used, because it not only increases the intestinal tone but also increases peristalsis, which is undesirable in peritonitis in that the protective adhesions are likely to be broken down. Whereas prostigmine is of value in adynamic ileus not associated with peritonitis, it should not be used in adynamic ileus associated with peritonitis because of the reasons given. On the other hand, morphine is the ideal drug for use in peritonitis. It increases the intestinal tone without increasing peristalsis. In this way it overcomes the deleterious effect of intestinal dilatation incident to the adynamic ileus associated with peritonitis and at the same time does not favor the spread of peritonitis by breaking down the protective adhesions. Opium and its derivatives have been used for decades in the treatment of peritonitis. Standard treatment of typhilitis has long consisted of massive opianization. It has been previously thought that opium splinted the bowel and relaxed it, whereas in reality opium and its derivatives actually increase the tone of the bowel, and it is because of this action that morphine is beneficial in peritonitis. The dose of morphine depends on the age of the patient. For an adult from 0.016 to 0.02 Gm. (one-fourth to one-third grain) may be given every three to four hours. The patient should be kept narcotized with the drug. Because of its depressing effect on the respiratory center, it is desirable to give oxygen. Oxygen also has a definite decompressive effect on the intestine in that the inhalation of high concentration of oxygen favors the absorption of nitrogen from the intestine.

FRACTURE OF TUBEROSITY OF TIBIA AND ARTHRITIS

To the Editor:—A woman aged 54 suffered a twisting injury of her right knee. X-ray examination shows a compression fracture of the lateral tuberosity of the tibia. Treatment as advised by a specialist consists of an open operation elevating the compressed cartilaginous surface of the tuberosity and supporting it in its elevated position by means of bone blocks taken from the ilium or lower down in the tibia. The patient has had a preexisting degenerative arthritis involving among other joints the injured knee. I would appreciate a discussion of the possibility of the arthritis predisposing to the fracture and references in regard to the prognosis following surgery and as to the prognosis as regards the disability if surgery is refused. M.D., Washington.

ANSWER.—There is little evidence to be found in medical literature which would suggest that chronic arthritis is a predisposing factor in the production of fractures. Occasionally osteoporosis associated with arthritis may be a predisposing factor in the production of joint surface infarctions. This has occurred in osteomalacia or hyperparathyroidism in a number of reported cases. The recommendation to elevate the depressed cartilaginous surface of the tuberosity of the tibia is definitely in accord with the best surgical practice.

If the underlying bone is badly crushed or atrophic, introduction of a bone block would be indicated. Not uncommonly it is also advisable to remove the semilunar cartilage which may be torn or displaced as an additional complication in injuries of the type described.

As is well known, trauma to a joint with or without fracture is likely to produce some permanent loss of function. Because of the history of a preexisting degenerative arthritis the prognosis in this case, regardless of treatment, should be reserved.

SUGAR IN MEDICINES USED BY DIABETIC PATIENTS

To the Editor:—A problem that is arising with increasing frequency is the question of sugar content in various products used by patients with diabetes mellitus. For instance, the covering of one well known brand of ferrous sulfate is quoted by the manufacturers themselves as containing 6½ grains of sugar. Patients frequently ask about the sugar content of tooth powders and pastes, the powder used in causing adherence of dental plates and the like. Is it advisable to be particularly strict in the use of such preparations and is there a likelihood of disturbed control? M.D., Illinois.

ANSWER.—The quantity of sugar or other forms of carbohydrate on or in pills and medical powders is so insignificant as compared with the total carbohydrate in the diet as to be negligible. This does not hold for various liquid medicines in which sugar is sometimes present in large amounts.

If one of the pills mentioned does contain 6½ grains (0.4 Gm.) of sugar, two would contain even less than a gram, and six a day 3 Gm., which would be only one fiftieth of the usual amount of carbohydrate in the diabetic diet.

DANGERS FROM ENAMELWARE

To the Editor:—In *Queries and Minor Notes* in the August 31, issue of *The Journal* a question was asked on ill effects reported from chipped particles of enamel. Although the question seems to indicate an interest in possible physical damage, the answer includes possible chemical injury. The answer does not include a discussion of the possibility of antimony poisoning. It is rather common knowledge that antimony is used by many kitchenware manufacturers, sometimes in rather high concentrations in the production of kitchenware. The antimony gives a more opaque enamel and permits thinner application over the metal, which makes it desirable from the enamelers' standpoint. In cheap enamelware, however, acid foods extract this antimony and there is a definite danger of poisoning to any one eating such food. There are recorded outbreaks of this kind. Under these circumstances enamelware cannot be given an unqualified "clean bill of health."

G. I. Wallace, Ph.D.,
Department of Bacteriology, University of Illinois,
Urbana, Ill.

AGGLUTINATION WITH DYSENTERY BACILLUS

To the Editor:—In *The Journal* for October 19, there appears an inquiry concerning "Agglutination with Dysentery Bacillus." In the answer it is stated that the patient who has an agglutination which was typical for 1:160 with dysentery bacilli of the Flexner type has had a previous bacillary dysentery infection. Although this interpretation of the dysentery agglutination test holds true in many cases, it should be emphasized that a positive Flexner agglutination may be obtained in patients who present neither history nor evidence of Flexner dysentery. Certain individuals may have a relatively high titer of normal agglutinins for Flexner dysentery bacilli. Also the particular technic employed in setting up the test (time and temperature of incubation, and so on) may materially influence the result. Furthermore, because of antigenic relationship of the Flexner group of dysentery bacilli to other micro-organisms, for instance *B. alkalescens*, patients infected with the latter organism may have agglutinins in their serum giving a positive agglutination with Flexner dysentery bacilli. Erwin Neter, M.D., Buffalo.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, November 16, page 1744.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, Dec. 11. Sec., Dr. Charles B. Pinkham, 1020 N. St., Sacramento.

COLORADO: * Denver, Jan. 7-10. Applications must be on file not later than Dec. 23. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: * *Endorsement*, Hartford, Nov. 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

GEORGIA: Atlanta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 8-11. Sec., Dr. James A. Morgan, 48 Young Building, Honolulu.

IDaho: Boise, April 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 335 State Capitol Bldg., Boise.

ILLINOIS: *Written*, Chicago, Jan. 21-22. *Reciprocity*, Chicago, Jan. 23. Supt. of Registration, Dept. of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Bldg., Fort Wayne.

IOWA: Des Moines, Dec. 9-11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 10-11. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Dec. 3-5. Sec., State Board of Health, Dr. A. T. McCormack, 620 Third St., Louisville.

MARYLAND: *Regular*, Baltimore, Dec. 10-13. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homopathic*, Baltimore, Dec. 10-11. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: * Ann Arbor and Detroit, June 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, Jan. 21-23. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*, Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*, Helena, March 31. *Written*, Helena, April 1. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEVADA: *Reciprocity with oral examination*, Feb. 3. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 13-14. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 14-15. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 27-30. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH CAROLINA: *Reciprocity*, Durham, Dec. 10. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Columbus, Dec. 9-12. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, Dec. 11. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: * Portland, Jan. 14-16. Exec. Sec., Miss Lorraine M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Acting Sec., Bureau of Professional Licensing, Miss Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, Jan. 2-3. Sec., Division of Examiners, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: * Pierre, Jan. 21-22. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre.

TEXAS: Austin, Nov. 25-27. Sec., Dr. T. J. Crowe, 918-920 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 4-6. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON: * Seattle, Jan. 13-15. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WISCONSIN: * Madison, Jan. 14-17. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Feb. 3-4. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, Dec. 17. Sec., Dr. Robert L. Nugent, University of Arizona, Science Hall, Tucson.

CONNECTICUT: Feb. 8. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, April 21-22. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

IOWA: Des Moines, Jan. 14. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor, Detroit and East Lansing, Feb. 14-15. Sec., Miss Flora E. Dube, East Lansing.

MINNESOTA: Minneapolis, Jan. 7-8. Sec., Dr. J. Charnley McKinley, University of Minnesota, 126 Millard Hall, Minneapolis.

NEBRASKA: Omaha, Jan. 14-15. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Feb. 15. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH DAKOTA: *Examination*, Yankton, Dec. 6-7. *Endorsement*, Dec. 21. Sec., Dr. Gregg M. Evans, Yankton.

WASHINGTON: Seattle, Jan. 9-10. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WISCONSIN: Milwaukee, Dec. 7. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Maryland June Report

Dr. John T. O'Mara, secretary, Board of Medical Examiners of the State of Maryland, reports the written examination for medical licensure held at Baltimore, June 18-21, 1940. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. One hundred and forty-eight candidates were examined, 137 of whom passed and eleven failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1940)	84	82.1
George Washington University School of Medicine.....	(1939)	84	90.1
(1940) 78			
Georgetown University School of Medicine.....	(1933) 77,	(1939)	86
Howard University College of Medicine.....	(1938)		81

Book Notices

Handbook of Public Health Bacteriology and Chemistry: General Information Regarding Epidemiology, Collection and Shipment of Specimens, and Bacteriologic, Serologic and Chemical Procedures. Edited by M. S. Marshall, Department of Public Health, City and County of San Francisco, California. J. C. Geiger, Director. Second edition. Paper. Price, \$1.50. Pp. 150. San Francisco: J. W. Stacey, Inc., 1939.

The second edition of this useful manual retains the policy of brevity, conservatism and a careful selection of laboratory procedures. The consideration of epidemiology as a section has been omitted from this edition and epidemiologic points are considered in connection with each disease. The section on bacteriology of specific communicable diseases has been revised and discussions on chancroid, venereal lymphogranuloma and lobar pneumonia have been added. In the section on the bacteriology of shellfish the procedure of Dr. C. A. Perry of Baltimore is summarized. In the section on chemical procedures the phosphatase test for pasteurization is added. Notes on serology appear for the first time in the appendix. Other revisions and additions have been made without undue expansion of the manual. Every one engaged in public health work will find this condensed manual an invaluable and accessible source of practical information.

The Fundamentals of Nutrition. By Estelle E. E. Hawley, Ph.D., and Esther E. Maurer-Mast, M.D., University of Rochester School of Medicine and Dentistry, Rochester, New York. Including Table of 100-Calorie Portions. By Estelle E. Hawley, Esther E. Maurer and Herbert F. Van Epps, The Department of Vital Economics, University of Rochester, and Discussions of the Dietary Management in Specific Conditions. By Collaborators Associated or Formerly Associated with The University of Rochester School of Medicine and Dentistry. With a foreword by John R. Murlin, Ph.D., Sc.D., Professor of Physiology and Director of the Department of Vital Economics, University of Rochester. Cloth. Price, \$5. Pp. 477, with illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1940.

This book presents the subject of nutrition from a fresh point of view. Its contents are divided into five sections. The first section gives a brief but adequate discussion on energy metabolism and includes useful data and charts. The second section deals with the fundamentals of nutrition and includes three chapters, on classification of foods, calculation of energy requirement, the normal diet and low cost meals. Each chapter is concise, practical and down to date. Tables are used frequently to epitomize facts. The third section is devoted to diet therapy and includes discussions of the dietary management in specific disease by various physicians. The collaborators of this section are for the most part those associated with the University of Rochester School of Medicine and Dentistry and others who were formerly associated with the institution. These contributions are conservative in presentation and no attempt has been made to overemphasize the role of diet in the specific disease discussed. The discussions are short and to the point. The concluding chapter of this section is devoted to a discussion of vitamin and vitamin deficiencies. Each vitamin and the corresponding deficiency state resulting from its absence in adequate amounts are discussed in a clear and authoritative manner. The discussions are succinct and are presented in as practical a manner as possible. The fourth section is devoted to diet planning and includes a large amount of valuable and useful data. The authors have selected the 100 calory portion in preference to the 100 Gm. "share" or standard serving. They contend that the 100 calory portion establishes one common basis for comparison and in addition is easily visualized, since it is so frequently the average serving or simple multiple. These tables are useful and complete. The chapter on calculation of diets is clear and well done. Other chapters in this section include one

page discussions on the utilization of food and food exhibits. The concluding chapter provides the reader with some useful miscellaneous data that are not often found in the average textbook of nutrition. The fifth section is an appendix wherein one finds the most modern methods of evaluating the nutritional status of the patient, including vitamins. The chapter on commercial vitamin products is a practical and useful compilation of facts. The chapter on food hazards is well outlined. The concluding chapters are on recipes and food suggestions for special conditions and special diet instruction sheets. The bibliography after each chapter in the book is current and authoritative. The work is in reality a handbook which contains an adequate amount of epitomized descriptive material on each phase of nutrition. The authors have done an excellent job of editing and organizing. The material is conveniently presented in a concise, simple and practical manner. It is distinctly original and can be purchased with profit by those whose libraries are complete with textbooks on the subject of nutrition. The physician as well as the nutritionist and the dietitian will find the book most useful. It is an excellent reference work for the library of hospitals and medical schools on the subject of nutrition. Few textbooks on this subject contain such a wealth of facts and useful data.

Experimental Investigations in Serum Allergy with Reference to the Etiology of Rheumatic Joint Diseases. By Egon Bruun. Translated from Danish by Mrs. Clara Packness. Denne Afhandling er af det lægeriske Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København, 1939. Paper. Price, 24 Danish kroner. Pp. 229, with 49 illustrations. Copenhagen: Einar Munksgaard; London: Oxford University Press, 1940.

This book details the results of four years of research work in Copenhagen by Bruun, who attempted to corroborate the animal experiments of Klinge and others on "serum allergy" (inflammatory reactions in various tissues of animals sensitized to horse or other serum and treated with subsequent doses of the same serum). Of late a number of German and American workers have supported the hypothesis that allergy somehow takes part in the causation of chronic polyarthritis as well as rheumatic fever. Beginning in 1929, Klinge sensitized animals with subcutaneous injections of protein (fresh horse serum) and subsequently injected the antigen into knee joints of rabbits, producing in joints, heart, muscles, liver and other tissues lesions considered analogous to those of human "rheumatism." In the injected (but not in the noninjected) joints, acute phlegmonous and chronic nonsuppurative arthritis were produced; in heart muscle and valves, lesions appeared which included some resembling Aschoff bodies. The reactions varied in different animals depending largely on the number, size and timing of the subsequent doses of antigen. Not dismissing the role of bacteria in the production of human rheumatism, Klinge concluded that rheumatic joint diseases in man probably represent the reaction of allergically sensitive tissues to bacterial proteins.

Bruun has repeated and extended Klinge's experiments. Seventy-five rabbits were sensitized to sterile horse serum; then at varying periods they were subjected to one or more intra-articular injections of the same serum. With minor exceptions Bruun substantiated the results of Klinge. By varying the size, number and spacing of the injections he produced either an acute allergic inflammation (chiefly lymphocytic and not polymorphonuclear as in Klinge's cases) or a subchronic or chronic allergic inflammation not only in the injected joints but also in other tissues—heart, vessels, liver, spleen and muscles. In four animals allergic reactions were also found in the noninjected knee joint, producing what the author called "allergic polyarthritis." Giant cells of the foreign body and not of the Aschoff type participated in the myocardial reactions. In the uncomplicated experiments these inflammatory reactions were almost entirely "lymphohistiocytic" in type, but when short cold applications (ethyl chloride spray) were also applied to joints subjected to the injections of horse serum the resulting inflammation became largely polymorphonuclear, indicating that cold acted as a "parallergen."

Commenting on his results, the author discusses the role of the reticulo-endothelial system in allergic and immune reactions and sets forth the hypothesis that the large mononucleated or multinucleated, nonspecific, allergic macrophage giant cells, which

arise from normal resting histiocytes, proceed under specific influences to develop into different giant cell forms characteristic of the influence which provokes them. Thus, if an allergic giant cell is influenced by Koch's bacillus it will be converted into a giant cell of the Langerhans type; if the allergic macrophage giant cell is influenced by small tissue necrosis (such as may result from cold applications) there will probably appear a foreign body giant cell, and if it is influenced by streptococci there will probably appear an Aschoff giant cell.

In conclusion the author indicates a number of far reaching points of resemblance between sero-allergic tissue reactions in experimental animals and the pathologic changes encountered in rheumatic patients. Complete agreement between the results of experiments on serum allergy and human rheumatism cannot be expected, because in animal experiments nonbacterial allergy is purposely applied in order to determine the importance of the allergic factors, whereas in human beings it must be presumed that both the sensitizing and the provoking doses of antigen originate from bacteria. Although conclusive proof is not yet available, Bruun considers it probable that rheumatic joint diseases (that is, rheumatic fever and certain forms of polyarthritis) result from the action of bacteria (probably streptococci) in an allergically changed organism.

The report represents a great deal of careful painstaking work and should not be lightly regarded even by those who, in the current tradition, scoff at the widening application of "allergy." The author is obviously and somewhat annoyingly vague in his use of the terms "rheumatic diseases," "rheumatism" and "polyarthritis," but probably he is purposely vague as thereby he does not have to limit his vision prematurely. Since both myocardial lesions and chronic inflammatory lesions in joints (with pannus formation and partial ankylosis) were produced, the reader is permitted to infer that, if the author's hypothesis is valid, human rheumatic fever and chronic deforming polyarthritis may be rather closely related.

The author describes the technic used and the lesions produced in careful detail, perhaps in too much detail. There is a summary at the end of each of the five main chapters and another at the end of the book. Some condensation and less reiteration would have been possible without loss to clarity. The book is illustrated with excellent photomicrographs; had they been inserted in their appropriate and separate places rather than bound together toward the end of the book it would have been easier for the reader. About forty pages is given over to extracts from the animal necropsy records. A bibliography of 213 references is appended.

This study would have found a larger audience and been more readily available had it been published in an American or English medical journal devoted to experimental medicine or pathology. Those readers who will search for it in its present form will find it thought provoking and worthy of their serious consideration.

Surgery of the Hand: Wounds, Infections and Closed Trauma: A Book for the Practitioner and the Surgeon. By Marc Iselin, M.D., Surgeon, The American Hospital, Paris. Translated by T. M. J. d'Offay, M.B., Ch.B., F.R.C.S., Surgeon and Deputy Medical Superintendent, City General Hospital, Leicester, and Thomas B. Mouat, M.D., Ch.M., F.R.C.S., Surgeon, The Royal Infirmary, Sheffield, England. Cloth. Price, \$5.50. Pp. 353, with 135 illustrations. Philadelphia: Blakiston Company, 1940.

This translation brings to English and American students and practitioners Iselin's ideas on the treatment of injuries and infections of the hand and represents a serious attempt to raise the standards of treatment of injuries and infections of the hand. At the outset, in emphasizing the importance of the subject the author cites a number of cases of obviously neglected and badly treated cases. One wonders, however, whether French surgical practice is quite as casual and ill considered as one might conclude from the cases described. Chapters on tetanus and trophic and painful sequelae of hand injuries and a section on acute spreading infection have been added to the previous edition. The revised discussion of the treatment of wounds shows the marked influence of Böhler's teachings. The author's discussion of wounds loses some of its effectiveness in the manner of its presentation. Wounds due to aniline pencils, subungual hematoma, wounds with bone lesions and division of tendons are grouped in a single chapter

on wounds of the fingers, wounds of the thumb in another, and wounds of the hands in a third—divided into wounds of the thenar eminence, middle palmar region and so on. As a result of this confusion one has difficulty in obtaining a clearcut notion of the author's ideas concerning the proper treatment of uncomplicated injuries of soft tissues, tendon injuries or nerve division. Taken as a whole, this volume represents an unusually wide experience and serious interest in the subject of hand injuries and infections. It deserves whole hearted commendation.

Embalming Fluids: Their Historical Development and Formulation, from the Standpoint of the Chemical Aspects of the Scientific Art of Preserving Human Remains. By Simon Mendelsohn, F.A.I.C., Consulting Chemist, Cincinnati, Ohio. Cloth. Price, \$4. Pp. 166, with 8 illustrations. New York: Chemical Publishing Co., Inc., 1940.

The author has compiled an interesting and authoritative book, probably the first of its kind, for the practicing mortician. The subject matter includes a review of the historical development of embalming, some phases of the chemistry of putrefaction, the action, formulation and compounding of embalming fluids, the chemical and physical properties of preservatives, a few analytical methods, the determination of the phenol coefficient, a digest of jurisdictional regulations and a digest of American patents for embalming preparations. Some of the material has been obtained from antiquated and obsolete textbooks such as Barnes's *Art and Science of Embalming* (Chicago, 1905). An interesting section is that on the selective absorption of formaldehyde by different tissues, which has been taken from the master's thesis of G. M. Sleichter (University of Cincinnati, 1939). Much of the organic and analytical chemistry is beyond the scope of the average mortician. Physicians, especially pathologists; and public health workers would be interested in the data involving the preservation of bodies, the effect of chemicals on the bodies and the regulations in various states for the embalming and the transportation of bodies. The book is recommended to every practicing mortician, not for the purpose of having him prepare his own chemicals, but rather to give him a more complete understanding of the chemicals he uses.

Rheumatic Fever: Studies of the Epidemiology, Manifestations, Diagnosis, and Treatment of the Disease During the First Three Decades. By May G. Wilson, M.D., The New York Hospital and Department of Pediatrics, Cornell University Medical College, New York City. Cloth. Price, \$4.50. Pp. 595, with 79 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1940.

This is a record of the extensive experiences of the author with rheumatic fever and all its protean manifestations. Dr. Wilson has been a diligent student of this disease for more than twenty years and has had extensive and intimate clinical experience in heart clinics, wards and convalescent homes. The book is replete with observations and data that are seldom found in a textbook. While much of the material is distinctly original, the author has drawn on current contributions to enhance her discussions. The volume is organized into five parts and each part has a carefully selected bibliography. Part I is a brief but interesting historical survey of the subject and an excellent discussion of the epidemiology and etiology of the disease. Original investigations of Dr. Wilson and her collaborators relative to the etiology of rheumatic fever are recorded in some detail. Part II comprises a detailed discussion of the clinical and pathologic manifestations of rheumatic fever in childhood. The author presents numerous tables and graphic summaries to support and epitomize the text. Part III is a discussion of the course of the disease in the first three decades of life and concerns itself particularly with prognosis. As the basis for this discussion, 547 case records have been observed and critically analyzed. Her ingenious graphic presentation of data facilitates this presentation considerably. Part IV is a discussion of the diagnosis and functional classification of heart disease in children and part V is a discussion of the management of rheumatic fever with treatment and convalescent care receiving special emphasis. At the end of the book is a wealth of useful data arranged in tabular form on geographic incidence of the disease, epidemiologic and genetic analyses of rheumatic fever families, summaries of experimental protocols, technics of laboratory methods, values for red and white cells in children, blood pressure readings, Addis counts and special measures in nursing care and diets. While the author did not intend to write

a textbook or critical review of the subject, she has succeeded in presenting the reader with one of the most comprehensive and authoritatively documented discussions of the disease in print. The work reflects not only the painstaking and disciplined approach to the study of this disease but also a sound and critical evaluation of an immense amount of clinical and laboratory data. Dr. Wilson and her collaborators are to be congratulated for this contribution. It is a current source of facts about rheumatic fever in all its phases that should be eagerly sought by every practicing physician. This is a book that should be in every medical library.

Physiology of Micturition: Experimental and Clinical Studies With Suggestions as to Diagnosis and Treatment. By Orthello R. Langworthy, Lawrence C. Kolb and Lloyd G. Lewis. Cloth. Price, \$3.50. Pp. 232, with 49 illustrations. Baltimore: Williams & Wilkins Company, 1940.

After reviewing the anatomy of the bladder with particular reference to the nerve supply the authors present the evidence which has accrued during the past several decades with regard to the physiology of urination. The experimental work of others is discussed and the additional data which these collaborators have acquired from their own efforts is presented in detail. Throughout the text numerous illustrative case reports are given which include important cystometrographic evidence. Disturbances of urination of neurogenic origin are described in detail and theories as to the cause of the various symptoms presented by the particular type of case are advanced. A brief summary follows each chapter, emphasizing the important points which have been treated. This should serve as a valuable reference work for both advanced students and those urologists interested in learning more about the patient with obscure physiologic disturbance of the bladder mechanism.

Oral Surgery. By Sterling V. Mead, D.D.S., M.S., B.S., Second edition. Cloth. Price, \$12.50. Pp. 1,315, with 560 illustrations. St. Louis: C. V. Mosby Company, 1940.

This is the companion volume to Mead's *Diseases of the Mouth*, in which an attempt is made to treat oral disease from the surgical point of view. To this end the author discusses oral bacteriology, surgical technic, the sterile field, anatomic relations and other pertinent material. Adequate discussions are given of methods of extracting teeth, the treatment of fractures of the jaws, infections involving the mouth and neck and other items of interest in this field. One criticism may be directed toward this work, a defect which it shares in common with Mead's *Diseases of the Mouth*. The text is too long, it is too verbose and the author has an unhappy facility for complicating discussions of treatment with direct quotations from the current literature. This occupies an unnecessary amount of space, making the text unwieldy and difficult to read. Following each chapter is an extended bibliography, but many of the references cited are incorrectly spelled or misquoted. This careless handling of the bibliographic material greatly reduces the usefulness of the book for students. The volume is profusely illustrated with drawings and roentgenograms which are helpful. The book should be of interest to dentists, oral surgeons and others engaged in treating the diseases of the mouth and jaws.

Specific and Special Reactions for Use in Qualitative Analysis With Particular Reference to Spot Test Analysis. By F. Feigl, Ph.D., Consulting Chemist at the Research Laboratories for Fine-Chemicals, Nourypharma, Denver. Translated from a revision of the third German edition by Ralph E. Oesper, Ph.D., Professor of Analytical Chemistry at the University of Cincinnati, Cincinnati. Cloth. Price, \$3.50. Pp. 192. New York: Nordmann Publishing Company, Inc.; Amsterdam: Elsevier Publishing Company, Inc., 1940.

This is an excellent treatise on the theoretical considerations involved in the qualitative recognition of inorganic elements. The book is produced as a companion volume to the practical part by the same author, "Qualitative Analyse mit Hilfe von Tüpfelreaktionen," which has been translated into English. Likewise this work is an English translation of the third German edition together with some material from the forthcoming fourth German edition. This volume contains no technics utilized in qualitative analyses but discusses from a theoretical point of view the various factors affecting the sensitivity and specificity of reactions employed to recognize inorganic elements by the use of spot tests. Subjects such as types of complex chemical

compounds, masking of reactions, enhancement of reactivities, the effect of certain atomic groupings on specific activity and solubility, capillary phenomena and fluorescence analysis are taken up under chapter headings. To the student and teacher of qualitative micro-analysis this volume should be most welcome and helpful. Many suggestions can be obtained which will be of service in developing new tests—micro spot tests in nature—for the recognition of certain inorganic constituents in the presence of contaminants. Considerable discussion is given concerning organic complexes containing inorganic elements. This field is most promising not only qualitatively but also in quantitative analysis, as is manifest by the numerous quantitative technics now employing this behavior. The final chapter on fluorescence analysis gives many suggestions for further investigation. This is particularly fortunate, since this field promises to be quite fruitful to those interested in biometric assay problems. This book seems of value to the pure analyst rather than to the clinician or clinical pathologist. However, the toxicologist will find many useful theoretical considerations of spot tests which he may find advantageous. The volume contains an excellent bibliography and is free from typographic errors.

Standard Methods of the Division of Laboratories and Research of the New York State Department of Health. Augustus B. Wadsworth, M.D., Director. Second edition. Cloth. Price, \$7.50. Pp. 681, with illustrations. Baltimore: Williams & Wilkins Company, 1939.

The first edition of this work was widely accepted as a practical and dependable source of information on general and special technical laboratory procedures as used in the various branches of the Division of Laboratories of the New York State Department of Health. The second edition maintains this high standard with the addition of the new quantitative technic in the complement fixation tests, the revised colloidal gold test and new methods in the production, concentration and standardization of certain therapeutic serums. The book still remains one of the most current comprehensive and authoritative sources of information on laboratory methods in print and should be in the library of every health department laboratory and medical library.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Gastric Ulcer Allegedly Resulting from Burns.—In the course of his employment, May 8, 1937, Fickbohm, who was about 29 years old and in good health, washed a motor with kerosene. The kerosene ignited and Fickbohm suffered second degree burns of the forehead and arms, and third degree burns of the chest, face, ears, hands and shoulders. He received medical and hospital care and returned to work July 1, continuing at work until October 23. There was evidence, however, that during that period he was subject to fainting spells, that he coughed and spit up blood, that at various times he had to stay away from work and that his condition became progressively worse. On October 23 he quit work and went to Colorado to recuperate. On his return home again the following spring his condition seemed worse. April 2, 1938, he submitted to an operation, which revealed the fact that he was suffering from a perforated gastric ulcer. Four days later he died, the immediate cause of death, according to the attending physician, being diffuse peritonitis and bronchopneumonia. His legal heirs brought proceedings under the workmen's compensation act of Iowa to recover compensation for his death, basing their claim, apparently, on the theory that the burns received in the course of employment caused the ulcer and the peritonitis, which resulted in death. The district court, Woodbury County, Iowa, affirmed an award of compensation rendered by the industrial commissioner, and the employer and his insurance carrier appealed to the Supreme Court of Iowa.

From the expert testimony, said the Supreme Court, adduced at the hearing before the commissioner, it appears that gastric

ulcers as a result of external burns are of infrequent occurrence and do not often come to the attention even of experienced and busy practitioners. None of the physicians testifying at the trial, however, denied that this form of ulcer might follow external burns, although they stated that such a result occurred in only a small percentage of cases. Two physicians testified that in their opinion the probable cause of the ulcer and death was the burns, while four physicians were of a contrary opinion. The condition of the workman, as testified to both by lay witnesses and by the attending physician, exhibited symptoms which are those of an ulcer, and this fact was not disputed by any medical witness. There was evidence that when gastric ulcers are due to burns such burns create "a toxic condition which passes through the blood and affects the organs of the body." There was a contradiction in the expert testimony as to the time when such ulcers will develop, as well as to the ultimate fact—the cause of death. But from these contradictory opinions, continued the Supreme Court, and in consideration of all the testimony, the commissioner concluded that death was caused by the burns, in the course of and arising out of the employment. This finding, if based on disputed questions of material fact, was conclusive on this court.

The Supreme Court accordingly affirmed the award of compensation.—*Fickbohm v. Ryal Miller Chevrolet Co. (Ia.)*, 292 N. W. 801.

Medical Practice Acts: Pardon No Bar to Subsequent Proceedings to Revoke Physician's License.—In November 1929 the plaintiff, a licensed physician in the state of Florida, was convicted in a Florida court of perjury, possession of stolen goods and grand larceny and was sentenced to imprisonment in the state penitentiary for five years. In March 1933 he was granted a full and complete pardon for such offenses by the board of pardons of Florida. Subsequently the defendant, the state board of medical examiners of Florida, commenced proceedings to revoke the plaintiff's license to practice medicine on the ground that he had been convicted of a felony. The plaintiff thereupon petitioned the Supreme Court of Florida for a writ of prohibition to restrain the defendant from continuing the revocation proceedings. The board then filed a demurrer to the petition.

The plaintiff contended that his full and complete pardon constituted a complete defense to the revocation proceedings and deprived the board of all jurisdiction to conduct further hearings in the matter. The modern trend of authorities, said the Supreme Court, is that a pardon restores one to the customary civil rights ordinarily belonging to a citizen of the state, i. e., the right to hold office, to vote, to serve on a jury and to be a witness, but it does not restore offices forfeited nor property or interests vested in others in consequence of the conviction. Section 8495, Comp. Gen. Laws of Florida, 1927, specifically provides that a person receiving a full pardon shall be entitled to all the rights of citizenship enjoyed by him before his conviction. The rights of citizenship, however, do not include the right to practice medicine and, said the court, we have been unable to find a decision by a court of last resort holding that a full and complete pardon restores the extraordinary right to practice any of the professions. The privilege of pursuing the practice of a profession, continued the court, is based on the granting of a license by a sovereign state, which license is granted only to those possessing the necessary integrity and approved moral character. The power of the Florida legislature to require, as a condition precedent to the practice of medicine, that the practitioner not only be learned in his profession but possess qualifications of honor and good moral character cannot be questioned. Likewise, it was a proper exercise of its power for the legislature to provide for the revocation of the license of a practitioner of medicine who has been convicted of a felony in the courts of Florida. The adjudication of a medical practitioner's guilt of felony renders him a man of such character as to render it unsafe to trust the lives and health of the citizens of this state to his professional care. The doors of our homes should not be opened to receive men who hold themselves out as qualified medical practitioners when in truth and fact they have been convicted of crime. Therefore,

since the pardon in the instant case merely returned the plaintiff to the rights of citizenship which he previously had, and since those rights did not necessarily include the right to practice medicine, the court held that the effect of the pardon should not be construed or extended to abrogate the provisions of the medical practice act, requiring moral qualifications of medical practitioners, by restoring to the plaintiff a license which he was no longer morally qualified to retain. Accordingly, the court sustained the defendant's demurrer and denied the plaintiff's petition for a writ of prohibition.—*Page v. Watson et al. (Fla.)*, 192 So. 205.

Evidence: Admissibility of Results of Chemical Tests for Alcoholic Intoxication.—The defendant was prosecuted for operating a motor vehicle while under the influence of intoxicating liquor. Over the objection of the defendant, the trial court admitted in evidence the results of chemical analyses of the defendant's urine and blood which had been made to determine the quantity of alcohol, if any, in those body fluids. On the basis of this evidence the defendant was convicted of operating a motor vehicle while in an intoxicated condition, and he appealed to the Supreme Court of Iowa.

The defendant contended that the effect of the admission in evidence of the results of the chemical tests for alcoholic intoxication was to compel him to be a witness against himself in that he had been compelled to give the specimens of blood and urine against his will. This contention, however, did not meet with the approval of the Supreme Court. Although the circumstances under which the specimens of blood and urine were obtained were not described in the published report, the court held that there was no evidence whatever of either compulsion or entrapment. In fact, said the court, the evidence showed that the defendant voluntarily gave the specimens in the hope that the results obtained by analysis would demonstrate that he was not intoxicated and thus free him from the charge brought against him. Accordingly, the judgment of conviction was affirmed.—*State v. Morkrid (Iowa)*, 286 N. W. 412.

Workmen's Compensation Acts: Student Nurse an Employee.—In the opinion of the Supreme Court of Wisconsin, a student nurse who pays the hospital where she is to receive her training a nominal entrance fee and a determined amount for books and uniforms to be used during the training period, who must render certain services to the hospital during that period and who is furnished board, room and laundry by the hospital is an employee of the hospital. An injury to such a student nurse arising out of and in the course of such employment, consequently, is compensable under the workmen's compensation act of Wisconsin.—*Employers Mut. Liability Ins. Co. v. Industrial Commission (Wis.)*, 292 N. W. 878.

Society Proceedings

COMING MEETINGS

- American Society of Anesthetists, New York, Dec. 12. Dr. Paul M. Wood, 745 Fifth Ave., New York, Secretary.
- American Student Health Association, Ann Arbor, Mich., Dec. 27-28. Dr. Ralph I. Canuteson, University of Kansas, Lawrence, Kan., Secretary.
- Annual Congress on Industrial Health, Chicago, Jan. 13-15. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otological Society, Philadelphia, Jan. 10. Dr. N. S. Weinberger, Robert Packer Hospital, Sayre, Pa., Chairman.
- Puerto Rico, Medical Association of, San Juan, Dec. 13-15. Dr. David E. Garcia, P. O. Box 3866, Santurce, Secretary.
- Radiological Society of North America, Cleveland, Dec. 2-6. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society of American Bacteriologists, St. Louis, Dec. 27-29. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Section, American Laryngological, Rhinological and Otological Society, Nashville, Tenn., Jan. 8. Dr. William G. Kennon, Doctors Bldg., Nashville, Tenn., Chairman.
- Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Surgical Association, Topeka, Kan., Dec. 6-7. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Vitamin C in Epilepsy: Dilantin Sodium Not a Cause of Vitamin C Deficiency. H. H. Merritt and Althea Foster, Boston.—p. 541.

Acute Nephritis.—Hayman and Martin maintain that the conception of acute glomerular nephritis as a disease of children which follows severe infections, especially scarlet fever, and is characterized by albuminuria, hematuria, edema and convulsions has been shown to be inadequate. While acute nephritis is more common in children than in adults, it may occur at any age. Moreover, not only is the prognosis more serious in the older age groups but the onset is frequently more insidious and the symptoms less dramatic. The authors describe the symptoms and clinical course of seventy-seven cases of acute glomerular nephritis treated in Lakeside Hospital from 1931 to 1939. All age groups were represented. A history of preceding infection was obtained in seventy-five of seventy-seven cases. Infection of the upper respiratory tract, sinuses and ears accounted for fifty-six (75 per cent). While the disease occurs at all ages, it is most common before 30. The cardinal symptoms of hematuria, hypertension and edema were not all present in every case. Evidence of cardiac involvement was present in approximately half the cases. Ten patients died in the hospital, seven (9 per cent) primarily of acute nephritis. Fifty-two of the remaining sixty-seven patients were followed for from six months to eight years. Of these thirty-five (67.3 per cent) are well, nine (17.3 per cent) have persistent albuminuria or hypertension, while three have died of uremia since discharge from the hospital, and five have chronic glomerular nephritis.

Clinically Associated Deficiency Diseases.—Spies and his associates report observations on 1,250 malnourished persons. The subjects were selected from persons presenting themselves for examination either at the Hillman Hospital, Birmingham, Ala., or the General Hospital, Cincinnati. The patients made frequent visits to the clinic, during which they

were weighed and examined. Diagnosis of a specific deficiency state was based on the presence of symptoms characteristic of it. Thus diagnosis of pellagra was made only if characteristic mucous membrane lesions, dermal lesions or both were present; diagnosis of riboflavin deficiency depended on the presence of characteristic angular lesions of the mouth, or ocular symptoms; diagnosis of beriberi was made only in the presence of nutritional neuritis. The diagnosis in each instance was confirmed by the response of the patient to the specific therapeutic agent administered under controlled conditions. In general, the method of confirmation consisted in the dramatic response to the administration of synthetic nicotinic acid or its compounds, synthetic riboflavin, synthetic thiamine hydrochloride or synthetic vitamin B₆, the patient's diet remaining constant. Many of these patients had other diseases, such as scurvy, which was treated with synthetic ascorbic acid, and vitamin A deficiency, which responded to carotene or oleum percomorphum. That many of these persons must suffer from general malnutrition even though they have no symptoms of a specific deficiency disease is indicated by an analysis of the dietaries of fifty cases which shows that they are deficient to some extent in each of the essential nutrients. These patients have mixed rather than single deficiency disease, and months and years of ill health precede the diagnostic lesions of a specific deficiency. The authors believe that the confusion regarding vitamins or deficiency diseases is partly due to the discovery that vitamin B, formerly considered a single substance, is composed of twelve or more separate factors, each, together with unknown substances, contributing to the total effect of therapeutic agents such as yeast, wheat germ or liver extract. Although the administration of a single chemical substance was followed by a response of the lesion for which it was specific and by a great increase in the patients' strength, the improvement in general was greater when they were given a number of synthetic materials than when they were given any one alone. Furthermore, when supplements of dried brewers' yeast powder or liver extract were given in addition to synthetic materials to persons who continued to eat their usual inadequate diets, there was an even greater improvement in their general health.

Coincidence of Tuberculosis of Endometrium and Lung.—Lackner and his associates studied the endometrium of 125 women suffering from pulmonary tuberculosis. Clinically two groups of tuberculous endometritis can be distinguished. The first is involvement associated with progressive

tuberculosis of the ovaries, the tubes or both. The endometritis represents only an associated pathologic process of minor clinical importance. The second is tuberculosis of the endometrium with normal tubes and ovaries, associated with and developing from a tuberculous infection of an organ outside the pelvis, such as the lungs and lymph nodes. This represents an important and obviously unsuspected syndrome of primary extragenital tuberculosis. It is in the latter group that the authors tried to determine how often women with primary progressive tuberculosis of the lungs would show an isolated clinically latent tuberculosis of the endometrium. Only women with evident progressive tuberculosis of the lungs, with no clinically manifest inflammatory process of the ovary or tube, were examined. Only two cases of manifest primary endometrial tuberculosis were found among the 125 women. The history and clinical observations of these two cases are meager and resemble that of most of the cases of tuberculous endometritis gleaned from the literature. Both patients apparently had normal or almost normal menstrual cycles. They had no gynecologic complaints. Vaginal examination was negative in one case and it elicited minimal changes in the other case. The incidence of two cases among 125 harmonizes with the figures obtained from the necropsy records of the Cook County Hospital during the last ten years. The incidence in the necropsy material was 1.87 per cent as compared with 1.6 per cent in the clinical material. The authors use Ghon's classification. In the first type with endogenous spread a generalized infection, with the local tuberculosis representing only a part of the generalized infection, must be distinguished from an isolated hematogenic focus or metastasis. The second type of endometrial tuberculosis represents "reinfection" and is represented by cases of a new infection in some other organ after a primary focus has developed in one organ. The two cases reported are classified as isolated metastasis of a primary pulmonary process. By exclusion the hematogenic route must be accepted as the method of spread. It may be similar to the spread of miliary tuberculosis, the difference being that the circulating tubercle bacilli found the endometrium the only favorable nidus. An example of this type of secondary tuberculosis is hematogenic salpingitis. The authors believe that the occurrence of an isolated hematogenic tuberculous endometritis would appear to be proved by the observations in their two cases.

Pelvic Tuberculosis.—Lahmann and Schwartz believe that tuberculous involvement of the female genitalia is more prevalent than is generally assumed. It has been estimated as constituting from 5 to 8 per cent of all pelvic inflammatory conditions and therefore should be considered in the differential diagnosis of any disorder of the female genitalia. Symptoms and signs are not typical and resemble those of many other maladies affecting the genitalia. Genital tuberculosis is usually secondary to tuberculosis elsewhere in the body and occurs most frequently during active sexual life. There is a marked tendency for the disease to descend from the tubes to the endometrium, involving the tubes in 90 per cent, endometrium in 75 per cent, ovaries in 30 per cent, cervix in 5.5 per cent and vagina and vulva in 0.5 per cent. There is no tendency for the disease to spread to the urinary tract. During a period of eleven years twenty-one women with tuberculosis involving the genitalia were admitted and treated at the Milwaukee County General Hospital. Positive evidence for the diagnosis could not be obtained in six instances as no tissue was available for microscopic study, and these have been excluded from discussion. Twelve of the fifteen were between 20 and 30 years of age. The oldest patient was 43. Not even in one instance was the diagnosis of genital tuberculosis correctly made or even considered preoperatively. In only one case was the diagnosis made by the operating surgeon. Symptoms of tuberculosis of the female genitalia resemble those of chronic gonorrheal salpingitis. The two most common complaints were pain in the lower part of the abdomen confined to one or both sides, and vaginal discharge, usually of long standing. Other symptoms in their order of frequency were loss of weight, urinary distress, vomiting, weakness, cough, abdominal mass, fever and chills. Eight patients are alive and well, including one on whom a right salpingo-oophorectomy

was performed in 1930 when the patient was 27 years old. Four patients could not be located and the remaining three are known to be dead. There was a high incidence of immediate postoperative complications. The most serious of these was draining sinuses from the incision, many fecal in character and of long standing. Sinuses which drained from approximately four months to four years developed in eight patients. Six of the surgical incisions healed primarily. Pelvic tuberculosis, according to the authors, may be spread by (1) contiguity, from the soft tissues adjoining the pelvis, (2) lymphogenically, usually from the abdominal cavity, (3) hematogenically, from some distant focus and (4) primarily, with direct inoculation by coitus. The only case of tuberculosis of the cervix (probably primary) that was encountered is cited. Pulmonary involvement was encountered in 20 per cent of the patients.

Bronchopneumonia.—Waters believes that with rare exceptions pulmonary morbidity follows a period of interference with normal respiration whether due to drugs, trauma or illness. Many of the signs and symptoms seen in patients depressed by illness or trauma are also observed as side effects of drugs administered to relieve pain. Illness, injury and pain therapy may interfere with normal breathing by interfering with the normal innervation, psychic activity, muscle tone, activity of the respiratory center and inhaled atmospheres. Improvement in the incidence of pulmonary morbidity lies along the line of preventing these complications and not in the treatment of bronchopneumonia after it is established. So far the occasional occurrence before, during and after anesthesia of a period of interference with normal respiration has not been prevented. Patients are still encountered who after operation, after sedative and narcotic drug administration, after head injuries or even during debilitating illness have atelectasis, massive collapse, bronchopneumonia and other major respiratory disease. Delay in the care of abnormally functioning respiration is fatal. Changes in pulse rate, respiration, blood pressures and body temperature afford earlier evidence of the onset of trouble than do cyanosis and auscultatory or percussion evidence. Such changes can be masked by oxygen therapy. Careful inspection of the respiratory movements viewed from the foot of the bed, laterally and from the head may make evident the asymmetry which is the cardinal sign of atelectasis. Similar management has been useful for prophylaxis and therapy. All markedly depressed patients should be treated by the "stir-up regimen." This means the hourly insistence on making the patient take several deep breaths and cough effectively, and changing his position radically. Active aid and encouragement by the attendant is required. Frequently a depressed patient with inactive breathing and inefficient or absent cough can be made to expel large quantities of secretion from the air passages. One may cause the unconscious or completely uncooperative patient to take several deep breaths by pouring pure carbon dioxide from a rubber tube held over the face. Such a flow of gas added to the inspired air may force the desired ventilation of inactive alveoli. Carbon dioxide is of therapeutic value for this specific purpose. When there is the slightest evidence of obstruction or of atelec-

tasis, tracheobronchial toilet, aspiration of secretions, is justified. This apparently drastic regimen, when instituted early and faithfully, has reduced the incidence of major respiratory complications and has reduced the severity of many of those still encountered. Markedly depressed breathing must be made adequate either manually or mechanically. Carbon dioxide therapy is not a physiologic remedy for depressed breathing. Oxygen therapy is logical for only half of the picture and may require supplemental augmentation of respiratory exchange to restore normal conditions.

Hyperthermia Following Anesthesia.—Burford encountered three instances of excessive hyperthermia in children following ether anesthesia during hot weather. Frequent records of temperature taken during anesthesia showed numerous moderate but unimportant elevations. They indicate that ether anesthesia, contrary to the opinion widely held, does not lower body temperature. These frequent moderate elevations and the cases of high temperatures suggest that under propitious conditions the factors working toward disturbance of thermal control during anesthesia become accentuated. The rise in temperature to around 108 F. is accompanied by a remarkable elevation of pulse and respiratory rates. One of the author's cases terminated in death. The condition is probably due to the simultaneous disturbance of heat production, heat loss and integration of the activities of the central nervous system related to temperature regulation. The adequate integration of these complex processes between heat production and heat loss requires continuous control by the central nervous system. The control of this diverse activity is centered in the hypothalamus. Abnormalities of heat regulation develop subsequent to lesions at the base of the brain involving the hypothalamus. Specific subdivisions of the hypothalamus control separately heat production and heat distribution. In hot weather, dispersion of heat is accomplished with difficulty, especially in children. Radiation and convection from the skin ordinarily account for the largest part of heat loss. On hot humid days, when the atmospheric temperature approaches the body temperature, the effectiveness of these mechanisms is curtailed. Vaporization from the skin then becomes the chief means of cooling the body. Vaporization during anesthesia meets certain man made impediments. As a result of complete draping during operation, convection and radiation are made more difficult and vaporization can become effective only after perspiration has moistened at least two layers of overlying sheets. The perspiration of a small child may not be sufficient to accomplish this. Vaporization from the skin of the face and from the lungs is impaired by the anesthetic mask and the anesthetist's arm. The administration of ether is associated with a marked adrenergic response, and the internally secreted epinephrine increases tissue metabolism and heat production. Secretion of the thyroid may also be increased through an ultimate effect of an original adrenergic response. This total effect on elevation of temperature achieves significance only through the coexisting impairment of heat distribution. Added to this, the control of the central nervous system on heat regulation may be faulty. Heat regulation in infants and small children is notoriously erratic. This may be related to the immature development of the central nervous system or of certain of its tracts. The three mechanisms of heat control can become affected in the course of anesthesia. The elevated rate of combustion of tissue is possibly aided by struggling during induction. The small rise of temperature is uncompensated. For each rise of 1 degree F. in body temperature, an increase of 7 per cent in the basal metabolic rate occurs. This adds to the production of heat which is already uncompensated. Thus a vicious cycle is established: increased heat causing increased metabolism and increased metabolism producing increased heat. This continues until the cycle is broken. Otherwise high temperatures are attained that produce either permanent damage to the central nervous system or death. The author studied the incidence and direction of changes in temperature of fifty patients during operations performed during the winter under various anesthetic agents and lasting three fourths of an hour or more. There were thirty-three elevations of temperature. Twenty of the elevations were probably no greater than those that normally develop in normal

individuals not under anesthesia; however, the five elevations of from 2 to 3 degrees F. are well beyond the normal range. In twenty the rise was less than 1 degree F. and in eight it was from 1 to 1.8 degrees F. Excessive hyperthermia occurs rarely enough to cause great concern, but when infants and children are scheduled for prolonged operations under ether anesthesia during hot weather the possibility of its development should be considered, and axillary temperatures made a part of the anesthesia record might provide a timely warning.

Bronchostenosis Complicating Asthma.—Prickman and Moersch believe that bronchostenosis, a definitely localized stricture-like narrowing of a bronchus, is more common than is generally observed. Bronchostenosis is primarily inflammatory and is not referable to allergic edema or bronchial spasm. The lesion inhibits the movement of air entering or leaving the segment of pulmonary tissue beyond the stenosis and retains bronchial secretions below the stenosis, so that an area of partial or complete atelectasis results. Among 140 patients suffering from asthma, examined with the bronchoscope, sixty were found to have definite stenosis of one or more bronchi. A study of these patients showed that bronchostenosis complicating asthma generally produces characteristic symptoms and, frequently, physical and x-ray signs. One prominent symptom is severe, persistent and sometimes paroxysmal cough. At first it is impossible for the patient to raise sputum and when it appears it is profuse, usually mucopurulent and in 40 per cent of the cases is at some time streaked with blood. The severe coughing is apparently caused by the patient's attempt to raise secretions retained by the stenotic area and later, when the stenosis recedes (spontaneously or because of bronchoscopic dilatation) the retained secretions are more easily raised. The sputum is probably blood tinged because of the bronchial inflammation and secondary pulmonary congestion which is present. Febrile episodes, either with or without preceding chills, occurred in 68 per cent of the cases. The fever is explained by the toxicity from the retained secretions and the inflammation. Febrile episodes, hemoptysis or purulent sputum do not accompany uncomplicated asthma and therefore the presence or history of any one of these features in asthma should suggest bronchostenosis or some other organic complication. Of the sixty patients, 53 per cent gave a history of pneumonia and 35 per cent of pleurisy. Bronchostenosis is frequently mistaken for bronchopneumonia. Roentgenograms of the thorax may show an area of pneumonitis or atelectasis. After the acute phase subsides, bronchoscopic examination reveals a stenosed bronchus and dilatation by forceps introduced through the bronchoscope, and aspiration of the retained secretion usually relieves it. An adult or a child who has asthma and who experiences one attack or repeated attacks of "pneumonia" should be suspected of having had stenosis of a bronchus until proved otherwise. The physical signs which may accompany bronchostenosis are secondary to the atelectasis. They consist of suppression of breath sounds and fremitus over the affected area and dulness to percussion over the atelectasis. In uncomplicated asthma physical signs are equal in each lung. The x-ray observations of bronchostenosis are

usually those characteristic of atelectasis or, less frequently, bronchiectasis. Only a few patients with asthma require bronchoscopy, but it should be done as it will rule out or confirm the presence of bronchostenosis. In addition to bronchostenosis caused by localized inflammation, bronchostenosis referable to malignant changes complicating allergic asthma, as was found in one of the sixty cases, tuberculosis or ulceration of calcareous material may be possible. Almost every case of bronchostenosis complicating asthma may be traced to an acute infection of the respiratory tract. Postural drainage is important when bronchial secretions are in excess. Daily postural drainage will help to correct the stagnation of secretions that apparently contributes to the development and aid in preventing recurrences of bronchostenosis. In half of the authors' patients the asthma had an allergic basis. The immediate results (relief of the patient, subsidence of fever, reduction in amount and improvement in character of the sputum, improvement of the asthma and often immediate reversal of physical signs of bronchial obstruction) of dilation and aspiration are excellent.

Pharmacologic Treatment of Schizophrenia.—Katzenelbogen and his colleagues present their experience with the following aspects of insulin shock therapy of schizophrenia: sensitivity to insulin, reactions following individual injections, unusual reactions (hazards) during and following individual treatments, biochemical studies, electro-encephalographic studies and therapeutic results. 1. Both men and animals may be hyposensitive or hypersensitive to insulin. The amounts necessary to provoke shock or hypoglycemic reactions varied from 25 to 400 units. Tolerance to insulin may change throughout the treatment. 2. The most common vegetative system reactions, profuse perspiration and abundant salivation, are usually simultaneous. The cardiovascular system responds with marked fluctuations in the pulse rate. The respiratory system usually does not show significant changes in the precoma phase of the treatment, but in the comatose state irregular, stertorous and deep heavy breathing is frequent. The body temperature more often than not goes down. General muscular relaxation or rigidity is frequent before and during the comatose state. Abolition of the corneal reflexes, weakening of the plantar reflexes or marked extension of the big toe are common during coma. The most dramatic reactions are excitement, motor restlessness, clonic convulsions and drowsiness. Usually each patient reacts along the same pattern throughout the treatments, but the quality, intensity, sequence and duration of the reactions may vary in different patients and in the same patient on different days. 3. Eight of the authors' 140 patients had unusual reactions: cardiovascular collapse, prolonged deep coma, apnea and cyanosis. Only one of these patients died. 4. Biochemical studies show that of the thirty-two variables analyzed in blood before the administration of insulin and during coma some showed changes during therapy beyond normal fluctuation and errors of the methods. Serum solids showed a tendency to increase, while the other blood constituents showed a definite decrease and then a trend toward the original level. Sugar and fermentable sugar diminish considerably and remain at a low level throughout the individual treatments. The blood sugar and inorganic phosphorus curves do not keep pace throughout treatment, the sugar curve remains low and the phosphorus rises gradually to the original level and in some cases above that level. The relationship between the hypoglycemia, the reactions and the dose of insulin are not qualitatively or quantitatively consistent. 5. The fifty brain action potentials studies in seventeen schizophrenic patients revealed two distinct types of "brain waves." In the first (in forty-two records) a fairly normal alpha rhythm, from eight to ten cycles per second, predominated during the earlier interval of recording. This was followed by a gradually steady decrease as the hypoglycemia progressed. Within a few hours of insulin injection a low frequency brain wave pattern averaging three cycles per second became predominant. There was a striking parallelism between the variations in the brain potentials and the changes in the blood sugar content. With intravenous dextrose the brain wave pattern often returned to its original preinsulin type within ten minutes; with gavage the return was longer but did not exceed thirty minutes. 6. Thirty-five of the patients were completely free from psychotic symptoms and made satisfactory adjustment

outside the hospital. Twenty-five patients were improved to the extent that there was a markedly favorable change in their behavior, with satisfactory social adjustment in the hospital and under certain favorable circumstances outside the hospital. The remaining patients showed no change. Twenty-four of the patients with remissions had been affected one year or less.

Blood Pressure Studies of University Students.—Thacker studied blood pressure records of 15,000 male university students and tried to ascertain the effect of exercise on them from a comparative standpoint. A systolic blood pressure over 150 mm. of mercury on entrance was considered hypertensive and one below 108 hypotensive. Exercise tests were not performed by students with discernible organic heart, kidney or thyroid disease. The same type of exercise, consisting of raising the weight of the body twenty times from the floor on to a chair 18½ inches high at the rate of forty cycles per minute, was performed by all subjects. The comparative effect of exercise was studied on the ninety-six hypertensive, fifty-six hypotensive and 128 normal subjects on whom the cold pressor test had been conducted for vasomotor response. The systolic blood pressure of 20 per cent of the hypertensive students increased more than 60 mm. of mercury and in 2 per cent the increase was more than 80 mm. The systolic pressure in the normal group failed to increase more than 50 mm. in 82.7 per cent and in none did it rise more than 60 mm. In the low blood pressure group, 91.6 per cent failed to show an increase of more than 30 mm. and none more than 40 mm. The average increase of the systolic pressure was respectively 48, 37 and 23 mm. of mercury for the hypertensive, normal and hypotensive classes. The diastolic pressure decreased in all three groups; more than 91 per cent of the normal and hypotensive students and 79 per cent of the hypertensive subjects did not have more than a 10 to 20 mm. decrease. Only about 8.5 per cent of the normal and low pressure groups had a diastolic decrease of 21 to 30 mm. as compared to 18.7 per cent of the hypertensive subjects. Following exercise the systolic pressure of the normal group returned to the basal level within five minutes as compared to only 78.8 per cent of the high pressure group and 74.8 per cent of the low pressure group. The pulse rate following exercise of the normal and low pressure cases returned to the basal level within two minutes; the average for the hypertensive cases was three and one half minutes. The average pulse rate increase after exercise was respectively thirty, thirty-four and thirty beats per minute for the high, normal and low pressure groups. The increase in the blood pressure cannot be attributed to this factor alone, as in many subjects a marked increase in the systolic blood pressure existed with only a slight increase in the pulse rate, and vice versa. The maximal average systolic pressure after exercise in the hypertensive group rose 30 mm. above the ceiling reached when the cold test was used. The regular or usual systolic blood pressure in the hypertensive class was 28 mm. above the basal level as compared to 5 and 7 mm. in the low and normal groups. From a detailed history of the students it was observed that 11.7 per cent of the normal, 14.3 per cent of the low pressure and 43.7 per cent of the hypertensive groups presented evidence of being nervous or easily excited. Also 3.1 per cent of the normal and 5.3 per cent of the low blood pressure and 54.1 per cent of the hypertensive groups gave a history of familial hypertensive cardiovascular disease. Likewise 17.8 per cent of the hypotensive class gave a family history of low blood pressure, whereas none of the high blood pressure and only 2.3 per cent of the normal subjects indicated such a familial disturbance. Perhaps the definite hereditary pattern for blood pressure depends for the most part on some structural or physiologic phenomenon of the autonomic nervous system and/or endocrine function, which are passed through the germ plasma. Of the students in the high pressure group 35.4 per cent were heavy eaters, as compared to 14.8 and 14.3 per cent of the normal and low pressure subjects. The history of the amount of exercise or work done appears to be of little importance as a causative factor in the production of essential hypertension. The fallacy of one blood pressure test is revealed by the fact that 64.8 per cent of the students with a systolic pressure above 150 mm. at the time of their entrance physical examination had normal pressures at the first recheck, as were 82.2 per cent of the hypotensive subjects.

Fever and Vitamin B for Chorea Minor.—In view of the frequency of cardiac changes in chorea and the fear of untoward complications following eight hours' exposure of a child to a temperature of 104 F. or over, as recommended by Neymann, Stone reduced the fever time and increased the number of treatments. The factor of vitamin B deficiency was considered as a possible contributing cause in the development of cardiac involvement and the hyperirritability of the nervous system. The patient's diet was therefore complemented by the addition of vitamin B complex given orally, and in some cases by thiamine hydrochloride given intravenously. In the last three years the author has treated twenty children suffering from chorea. Seven patients exhibited all the signs of severe chorea, as manifested in continuous movement of the face and extremities, inability to feed or dress themselves, hypotonia and muscle weakness, and inability to walk without support. The other thirteen patients presented moderately severe or mild forms of the disease. A number of patients gave a history of an attack of severe chorea from three months to two years previously, from which they had apparently never completely recovered. The author's method of treatment for severe cases (an advanced cardiac condition was not found to be a contraindication to the treatment) consisted in giving the patient six or seven fever treatments, one every three or four days, and maintaining the temperature at 104 F. or over for about two hours. Every treatment was followed by the injection of from 10 to 15 mg. of thiamine hydrochloride intravenously shortly after removal from the fever cabinet, while the temperature still remained elevated. The patients received from 4 to 8 cc. of vitamin B complex orally three times daily. Recovery was produced with about fourteen hours of fever at 104 F. or over. When this was combined with vitamin B therapy, advanced cardiac conditions were found to be no contraindication to the fever treatment. Usually a change for the better in the carditis was noted at the end of the treatment. One of the two patients treated with thiamine hydrochloride responded with cessation of symptoms after the second intravenous injection of 10 mg. of the drug. Various degrees of behavior disturbances were seen in most of the moderately severe and milder cases. They all received from 4 to 8 cc. of vitamin B complex orally,

three times a day. The improvement in physical manifestations was less rapid than it was in the fever-treated patients, but most of the symptoms disappeared within one month. No hospitalization was required for any patient in this group. Improvement was noted in their behavior concomitantly with the change for the better in the choreic manifestations.

55:1707-1758 (Sept. 20) 1940

- *Rheumatic Heart Disease in Philadelphia Hospitals: Study of 4,653 Cases of Rheumatic Heart Disease, Rheumatic Fever, Sydenham's Chorea and Subacute Bacterial Endocarditis Involving 5,921 Admissions to Philadelphia Hospitals from Jan. 1, 1930, to Dec. 31, 1934: III. Fatal Rheumatic Heart Disease and Subacute Bacterial Endocarditis. O. F. Hedley.—p. 1707.

Rheumatic Heart Disease in Philadelphia Hospitals.—According to Hedley, of 4,653 cases (5,921 admissions) of rheumatic heart disease, rheumatic fever, Sydenham's chorea and subacute bacterial endocarditis admitted to Philadelphia hospitals from Jan. 1, 1930, to Dec. 31, 1934, 21.9 per cent ended fatally. If subacute bacterial endocarditis apparently not superimposed on rheumatic heart disease is excluded there were 916 deaths, or 20.2 per cent, among the 4,538 cases. Of 3,445 cases of rheumatic heart disease, excluding all subacute bacterial endocarditis, 732, or 21.3 per cent, terminated in death. Subacute bacterial endocarditis apparently not engrafted on rheumatic heart disease was the cause of death in 104, and of the 916 fatal cases of rheumatic heart disease 901 were due primarily to rheumatic heart disease including deaths from subacute bacterial endocarditis when occurring as a complicating factor. The causes of the other fifteen deaths were due to various causes, including empyema, traffic accidents, operations and diabetes, but had this study been based on postmortem examinations rather than clinical observations this percentage of 1.6 would probably have been substantially increased. With one possible exception, in no instance was death attributable to the arthritic manifestations of rheumatic fever or the cerebral manifestations of Sydenham's chorea. The mean age at death from rheumatic heart disease, regardless of its association with subacute bacterial endocarditis, was slightly less than 30 years. The proportion of deaths from rheumatic heart disease in hospitals among Negroes was not as great as might be expected. This is probably influenced by the age distribution of the Negro population as a result of recent migration. Among the 916 deaths more than 63 per cent occurred during the 10 to 19, 20 to 29 and 30 to 39 decades; more than 50 per cent of deaths occurred among persons less than 30 years of age, while only 3 per cent occurred among persons more than 60 years of age. The studies do not suggest that deaths from rheumatic heart disease in Philadelphia hospitals are more common among foreign born persons or among persons of foreign extraction than among old stock white Americans; if anything, the opposite obtains. This is probably influenced by the readiness with which various racial groups avail themselves of hospital facilities, their economic status and the relative age of foreign groups dependent on the period of greatest immigration. Fatalities from rheumatic heart disease were disproportionately high among the laboring classes. There were few deaths among professional men. As the disease develops during childhood, persons with rheumatic heart disease are not as likely to engage in occupations requiring strenuous exertion as the social status of the laboring classes would suggest. Rheumatic heart disease causes approximately 200 deaths annually in Philadelphia hospitals;

165 are due primarily to rheumatic heart disease, while thirty-five are due to subacute bacterial endocarditis superimposed on rheumatic heart disease. In about 0.1 per cent of hospital admissions for all causes, death is due to rheumatic heart disease. The mean age at onset was 14.7 years, the mode 9.3 years. The mean interval between the primary manifestation and death was 13.4 years. Among 542 fatal cases in which the duration from onset to death was ascertained, death resulted in less than one year in 13.5 per cent, in less than five years in nearly 32 per cent and in less than ten years in more than 48 per cent. At least from 3.5 to 4.5 per cent of first attacks terminated fatally. This percentage becomes higher if deaths from fulminating rheumatic carditis without arthritic manifestations of rheumatic fever are included. Despite the preeminence of Philadelphia as a medical center, the problem is a local one as at least 87.2 per cent of fatal cases were among residents. The mean annual death rate from rheumatic heart disease in hospitals among Jewish persons was approximately the same as among Gentiles. Of 116 pregnant women with rheumatic heart disease, 18.1 per cent died.

Night Blindness, Vitamin A Deficiency and Tuberculosis.—Harris and Harter studied the photometer readings of 114 ambulant institutional patients with pulmonary tuberculosis. The tests showed about an equal deficiency in vitamin A in the few newly admitted patients so studied. The diet in this institution has been carefully worked out and contains everything necessary to a point of luxury. The minimal reading of 0.6 was regarded as normal, from 0.6 to 2 as pathologically borderline and more than 2 millifoot candles as unmistakably pathologic. Of the patients tested, fifty were pathologic at the first test, sixty-one were borderline and three were normal. At the end of one week each patient having had 30,000 units of halibut liver oil daily, of thirteen pathologic cases tested eight were still pathologic and five borderline. At the end of three weeks, on the same dosage, nineteen of the originally pathologic patients were tested: four were still pathologic and fifteen fell in the borderline class. Of twenty-five originally pathologic patients tested after having been on 30,000 vitamin A units of halibut liver oil for two months, three were normal and twenty-two were high borderline. At the end of five months, of fourteen tested five were normal and nine very high borderline. Thirty-five of the originally pathologic patients were discharged before the end of five months. The author concludes that marked vitamin A deficiency in any individual might indicate that a thorough chest examination is in order if no other cause is found for the deficiency. Large doses of halibut liver oil may be necessary. Fifty and more years ago pulmonary tuberculosis was treated with cod liver oil and the physicians of that time were positive that it helped. Vitamin A in large doses may offer a worthwhile treatment in ocular tuberculosis.

Spontaneous Hyperventilation Tetany.—Fowweather and his co-workers have encountered five cases of spontaneous hyperventilation tetany. The serum calcium was determined as a routine measure in each of them and in four the serum inorganic phosphorus. In three the phosphorus was in the neighborhood of 1 mg. per hundred cubic centimeters of serum. The authors believe this figure to be much lower than previously reported in this type of case. The results in these three cases are so definitely below the normal range as to be of valuable diagnostic significance, making phosphorus determination a useful addition to the methods of diagnosis. The specimens of blood were taken immediately after an attack. The serum calcium in four of the cases was at a high normal level, while in the fifth it definitely exceeded the normal. The three patients whose blood was examined when they were free from attacks gave figures below those obtained just after an attack. The first three patients had attacks of tetany during the course of another illness, which may well have been a contributing factor in the production of the tetany or a precipitating cause of the attacks. Spasmodic attacks were the major complaint of the other two patients. Both patients were obviously of neurotic type—one "full of complaints" and the other giving a history of hysterical fits. To the authors the most probable explanation of spontaneous hyperventilation tetany appears to be as follows: As a result of certain stimuli—physical or emotional—some individuals respond by overbreathing. If this is sufficient to reduce the carbon dioxide concentration in the blood, alkalosis will follow and in its turn may be sufficient to cause an attack of tetany. The attack is mainly due to tissue alkalosis and ends spontaneously, largely as a result of the tendency to tissue acidosis consequent on the muscular activity of the tetany itself. Cessation of overbreathing also occurs and assists in the return to normal conditions. The principal factor is the tendency to overbreathe among those of emotionally unstable temperament, sufferers from anxiety neuroses and the like. The tendency may be influenced by physical factors. Other factors which probably play some part are the state of the acid-base equilibrium when the overbreathing takes place and the susceptibility of the subject to alkalosis and its effects. Conditions other than tetany which have been associated with hyperventilation have been described under the terms "neurocirculatory asthenia" and "effort syndrome." Therefore alkalosis resulting from spontaneous hyperventilation may cause either tetany or the conditions referred to. What determines the actual clinical manifestations in any given case is not apparent. However, (1) effort syndrome and related conditions without tetany are

rarely, if ever, seen as a result of voluntary overbreathing in normal individuals, (2) in spontaneous tetany resulting from hyperventilation and sometimes in the tetany induced by voluntary overbreathing in normal persons many of the symptoms (breathlessness, dizziness, faintness, palpitation, tremor) associated with effort syndrome and the like are also present but tend to be overshadowed by the tetanic spasms and (3) in cases of spontaneous hyperventilation tetany, effort syndrome and the like there is a background of anxiety, emotional stress or other psychologic disturbance.

Sulfanilamide as Preservative for Stored Blood.—Hunwicke confirms the experiments of Novak that sulfanilamide in comparatively low concentrations has a preservative effect on blood stored at refrigerator temperatures. Novak recommends the addition of 20 mg. of sulfanilamide to 100 cc. of blood. In one of the experiments reported by Hunwicke this did not prove adequate. The use of higher concentrations, say up to 1:1,000, would seem to offer a solution of the problem, provided the initial contamination is negligible. When complete sterility is achieved there is no need for any addition to the blood, but this is a rare condition as usually there are a few organisms present which do not reveal themselves until the blood has been in the refrigerator for some days or weeks, when they begin to multiply. It is to guard against wastage of blood and the possible consequent danger of heavy contamination that the addition of sulfanilamide is suggested. The sulfanilamide must be added to the blood in concentrated sterile solution. The solution when added to the blood must be still warm, that is before crystallization begins.

Immunization Against Whooping Cough.—Chu and Wu observed the effect of active immunization of thirteen children against whooping cough during an epidemic in a local orphanage. The thirteen children were inoculated at weekly intervals for three weeks with vaccine prepared from phase I organisms. About five months after the completion of the vaccination of these thirteen children whooping cough appeared at the institution. Facilities for the isolation of the orphanage children were entirely lacking. Of the thirteen children vaccinated prior to the outbreak none developed the disease in spite of continuous and prolonged exposure. On the other hand typical pertussis developed in twenty-three, or 67.6 per cent, of thirty-four non-vaccinated children whose age, mode of living and degree of exposure were the same as those of the vaccinated children. The serum agglutinin titer for *Haemophilus pertussis* increased during the course of the epidemic in seven of the vaccinated children, indicating clearly that they had been exposed. The remaining six vaccinated children likewise showed increased agglutinin titers, but they had been given an additional dose of vaccine during the early part of the epidemic. The authors are convinced of the effectiveness of the method for preventing pertussis.

Prevention of Prolonged Coma in Insulin Shock Therapy.—Accornero and Giordani report the successful use of 1-phenol-2-methylaminopropanol in preventing prolonged coma in eleven selected cases of dementia praecox (six of which were of the paranoid type) after insulin shock treatments. The drug, added to the sugar solution and administered by means of a stomach tube in doses varying from 6 to 12 mg., was able to reduce coma to periods varying from ten to twenty-five minutes in patients who previously had been observed to require fifty minutes and even six and a half hours to recover consciousness. Though given daily for as long as two months in high doses, the drug was well tolerated and elicited no untoward effects. Their three year experience with the drug proved that it had to be given in combination with the sugar solution. Delayed administration not only lowered efficacy but tended to negative results. The authors point out that in no case was prolonged shock due to overdosage with insulin. Prolonged shock, they believe, is likely to occur even when all precautions have been observed because of the variability of effect of the same dosage in the same person on successive days due to hypoglycemic fluctuation or to retarded absorption of the carbohydrates under the influence of excessive acidity of the gastric juice. They recommend that the drug be used to prevent prolonged coma in persons known to have a tendency to revive slowly rather than that it be relied on as a means to interrupt protracted coma after it has already set in.

*Identification of *Trichomonas vaginalis* in Leukorrhoeas. A. B. Corrêa Mendes.—p. 432.
Waterhouse-Friderichsen's Syndrome: Case. Silva Nunes.—p. 459.

Trichomonas vaginalis in Leukorrhoea.—Corrêa Mendes made a comparative study of stained dried smears of either fresh or dry vaginal secretions and microscopic preparations of fresh vaginal secretions of 120 women with leukorrhoea. Microscopic preparations were made with the vaginal secretion in physiologic solution of sodium chloride. The smears were prepared by the "roll film" method, allowed to dry, fixed by heat and stained by Jensen's modification of Grams method. The results of the two methods agreed in 116 cases, there being thirty-five positive results for *Trichomonas* and eighty-one negative results. In four cases *Trichomonas* was identified by the dried staining method alone, after failure of fresh microscopic preparations. The author believes that the methods of stained dried smears and of microscopic preparations of fresh vaginal secretion have the same diagnostic value in identifying *Trichomonas vaginalis*. The practical value of the smear method is greater than that of preparations of fresh secretion. Bacteria other than *Trichomonas* may be identified. In cases of *Trichomonas* infection reported by the author, the vaginal secretion did not contain Döderlein's bacilli. The vaginal bacterial flora corresponded to that of the third degree of Cruickshank and Sharman's classification. Control of protozoal infection resulted in a modification of the bacterial flora to the type which corresponds to the first degree of Cruickshank and Sharman's classification. *Trichomonas* was present in association with gonorrhea in three cases, with eumycetes in two and with spiriles in three cases. The vaginal secretion of twelve pregnant women contained eumycetes alone or in association with vibrios in the absence of *Trichomonas*. *Trichomonas* is identified in dried stained smears by the appearance of the protoplasm and by the position of the nucleus and the presence of stained flagella. The protoplasm is granular and foamy. The nucleus appears as an elongated mass uniformly stained red in the proximal end of the protozoon near the point of insertion of flagella, which usually, though not necessarily, takes the red stain.

Endoscopic Examination and Monaldi's Intravenous Aspiration.—Abelló, in discussing the technic of Monaldi's intracavernous aspiration (see abstract in THE JOURNAL March 9, 1940, p. 934) and the instruments used for this procedure, describes an instrument developed by him which enables one to inspect the interior of a cavity. The basic idea of the instrument is the use of the thoracoscope in connection with the Monaldi method. He designates his instrument as a cavernoscope or pleurothoracoscope. The instrument has the diameter of a No. 12 Nelaton catheter. The upper end of the lamp is constructed like Bottari's trocar and thus the thoracoscope can serve as a trocar. The instrument is introduced with the lamp lighted. In order to prevent the prism becoming clouded at the time it enters the cavity it is passed over an alcohol flame. The apparatus can also be used to close the drainage bronchi by means of diathermy. The author gives detailed description of the practical application of his method. Following roentgenologic localization of the cavity a Saugman needle is introduced at the most favorable point. The trocarthoracoscope is then introduced by the same course as the needle. Following inspection of the cavity, the cavernoscope is withdrawn and replaced by a rubber tube. The cavity should be entered, if possible, 2 or 3 cm. above the base, for if it is entered near the base it becomes easily stopped up. The position of the tube must be controlled by x-ray examination. Since coughing may cause misplacement or even expulsion of the tube, it should be attached to the wall of the thorax. The author advises twenty-four hours of rest before aspiration is begun.

*Nicotinic Acid Therapy in Pellagra of Children. P. S. Gershenovich, A. M. Maksudov and Ts. G. Ioffe.—p. 29.

Spontaneous Gangrene and Trophic Ulcers.—Shnaper treated fifteen cases of spontaneous gangrene of the extremities, twelve cases with trophic ulcers, two cases with circulatory disturbances due to chilblain and one case due to a snake bite. The patients with spontaneous gangrene complained of excruciating pain in the extremity, intermittent claudication, coolness and cyanosis of the extremity with the development of gangrene of the toes or the entire extremity. As a rule there was no pulsation in the dorsal pedal artery and in some of the cases in the popliteal. All the patients had been previously submitted to a number of medical and surgical procedures without success. The treatment consisted of a circular procaine hydrochloride block according to the method developed by Vishnevsky. From 200 to 225 cc. of a 0.25 per cent of procaine hydrochloride solution was slowly injected into the skin and subcutaneous tissue and below the aponeurosis in a circular fashion above the lesion. This procedure was followed by a mild rise in temperature, normal sleep and disappearance of pain within the first twenty-four hours. The pain returned after this period but was much less intense and disappeared gradually in from two to five days. The affected extremity became warmer and a line of demarcation rapidly developed in cases exhibiting beginning gangrene of toes or fingers. In some of the cases the circular block was supplemented within three weeks by a lumbar block (injection of from 75 to 100 cc. of procaine hydrochloride solution into the right or left lumbar region). The favorable effect was observed for periods of from one and one half to two years.

The rationale of the treatment is based on Speransky's theory that local irritation involves the central nervous system with the resulting upset in the normal internervous relations. He proposed the method of treating trophic lesions by interrupting the conduction of painful reflexes.

Nicotinic Acid Therapy in Pellagra of Children.—Gershenovich and his associates treated children with pellagra of the ages from 1 to 13 years in the pediatric clinic of Tashkent. The severe cases of pellagra presented clinical manifestations on the part of the skin, the gastrointestinal tract, the tongue and the nervous and psychic spheres. Children with subclinical pellagra presented diarrhea, lasting from two to six months and not yielding to ordinary dietetic therapy, marked dystrophy, asthenia, dryness of the skin and disturbances of pigmentation. The greater majority of the cases presented characteristic pellagrous glossitis with redness and erosions. The advanced pellagrins appeared emaciated, asthenic and apathetic and suffered from severe diarrhea and total anorexia. Nicotinic acid was administered intramuscularly in a 1 per cent solution in distilled water in doses of 1 cc. for a child aged 1 year, 2 cc. for a child aged 2 years, 3 cc. for a child aged 3 years, 4 cc. for a child aged 4 years, 5 cc. for children of ages from 5 to 10 years and from 6 to 8 cc. for children above that age. The injections were given daily, in some cases twice a day. From ten to fifteen injections were necessary to accomplish a cure. Among the accompanying reactions the authors noted hyperemia of the tongue, face, neck and the upper half of the thorax, developing shortly after injection of nicotinic acid and lasting from a few minutes to several hours. All the patients without exception had a normal appetite after from three to four days of treatment. The tongue became normal after from five to six days or earlier. There was cessation of vomiting and gaining of weight in every case. The authors had never observed such a striking gain in weight in pellagra under any other therapy. The effect of the nicotinic acid therapy on the subclinical cases was likewise manifested by a rapid return of the appetite, arrest of diarrhea, improvement in the general condition and a normal appearance of the tongue. The authors conclude that nicotinic acid possesses a powerful specific curative effect on both the well marked and the so-called subclinical cases of pellagra.

Hyperthyroidism After Use of Thyroidin for Reducing.—Andersen reports three cases of hyperthyroidism following the use of thyroidin for reducing which were observed at a Copenhagen hospital in the course of one year. The three patients were women past the menopause and all had received energetic treatment with thyroidin. They were hospitalized with severe signs of thyrotoxicosis and auricular fibrillation. The treatment proved more difficult than usual; only two could be brought into a condition suitable for operative treatment. In the third case, however, spontaneous improvement appeared about a year after the onset. Of the cases in which surgical treatment was employed, only one showed a fairly satisfactory response. The hypothesis is advanced that the protracted administration of thyroid might produce a dysfunction of the hypophysis with increased production of the thyrotropic hormone, so that these cases represent a hypophysial rather than a thyrogenic hyperthyroidism. This view seems to be supported by the fact that the enlargement of the thyroid was slight in all three cases and that they were strikingly refractory to the usual treatment. The uncommonly malignant character of the reported cases convinced the author that extreme caution is necessary in the use of thyroid preparations for reducing.

HYPERTENSION AND THE SURGICAL KIDNEY

WILLIAM F. BRAASCH, M.D.

WALTMAN WALTERS, M.D.

AND

HOWARD J. HAMMER, M.D.

Fellow in Urology, the Mayo Foundation

ROCHESTER, MINN.

In 1934 Goldblatt,¹ working in the physiologic laboratories at Western Reserve University, reported that partial constriction of the renal arteries of dogs was followed by a rise in blood pressure. Other observers previously had shown that hypertension was related to renal pathologic change, but no one ever had demonstrated it so graphically. Similar experiments were made subsequently in numerous laboratories, most of which confirmed the observations of Goldblatt.

Seldom have physiologic experiments attracted such immediate, widespread interest in medical circles. The etiology and the treatment of hypertension have presented problems which have baffled medical science for long and it is not surprising that any suggestion as to the cause and amelioration of this disease would create general interest. It was not long before Goldblatt's experimental observations were confirmed by clinical reports² of cases in which the blood pressure of patients with hypertension returned to normal after removal of a diseased kidney. These reports of cases seemed to prove that unilateral renal lesions may cause hypertension and that removal of the affected kidney often is followed by recovery.

It seemed to us that a review of a large series of cases in which there were renal lesions which had been subjected to surgical treatment would afford information concerning such problems as the following: (1) the incidence of hypertension in relation to the different types of renal lesions, (2) the postoperative course of the blood pressure in these cases and (3) the relation of hypertension to (a) renal stasis, (b) renal function and (c) bilateral renal involvement.

INCIDENCE OF HYPERTENSION AMONG PATIENTS WITH SURGICAL CONDITIONS OF THE KIDNEY

Before determining the incidence of hypertension in association with renal lesions it seemed desirable to

determine its occurrence in a random group of adult patients. A study was made of the blood pressure readings in 975 consecutive cases taken at random from the registrations at the Mayo Clinic (table 1). Adopting 145 mm. of mercury as the lowest level of abnormally elevated systolic blood pressure, we found that 195 of the 975 patients examined, or 20 per cent of the total, had hypertension. In deference to the opinions of some clinicians, we also kept records which would allow 160 mm. to be considered the lowest level of abnormally elevated systolic pressure (table 2). One is impressed with the influence of age in determining the incidence of hypertension, a factor which is not directly related to a renal lesion. Of the patients who were less than 50 years of age 9.1 per cent had hypertension, while of those who were 50 years of age or more 37.9 per cent had hypertension. Thus the incidence of hypertension in the older group was more than four times as great as it was in the younger group.

In order to determine whether the incidence of hypertension was increased by renal pathologic change observed in the so-called surgical kidney, a study was made of a group of 1,684 patients subjected to renal surgical procedures at the Mayo Clinic (table 2). In this group approximately the same percentage had hypertension as that observed in an average group of adult patients. It could be inferred that many renal lesions of a surgical type do not cause hypertension, since the incidence of hypertension in the group of patients subjected to surgical measures was not higher than that in the average group just mentioned. However, the influence of age on the incidence of hypertension again was found to be a factor, since the incidence of hypertension among patients with surgical kidneys was lowered by the slightly larger percentage of these patients who were less than 50 years of age.

A study of the 315 cases in which surgical lesions of the kidney were associated with hypertension showed that the incidence of hypertension varied widely among the various types of renal lesions concerned. Hypertension occurred most frequently in association with chronic renal infection which caused extensive atrophy of the renal tissues and sclerosis of the blood vessels. Renal infection was not an etiologic factor in hypertension unless it caused widespread atrophic changes in the renal parenchyma. Hypertension occurred much more frequently among patients with atrophic pyelonephritis than among those with any other renal lesion. Such sclerosis may occur either as the result of primary renal infection or secondary to some other renal lesion. The incidence of hypertension in association with surgical pyelonephritis, without atrophic changes, was less than half of that observed in association with diffuse atrophic changes. That some secreting renal tissue remain is necessary, since complete atrophy does not cause hypertension. It is of interest that hypertension afflicted only a small number of patients with acute

renal infection who were subjected to surgical operation; yet this lesion often involved both kidneys. The preoperative blood pressure was normal in all but one of the cases in which operation was performed for perinephric abscess.

In what follows, the number of cases representing the various lesions will not add to the total of 315, because not all types of lesions encountered will be discussed.

Atrophic Pyelonephritis.—In this group were few, if any, clinical data which would enable one to distinguish between the patients who had hypertension and those who did not have it. Although extensive renal and vascular sclerosis was found in most of the kidneys removed in the cases in which hypertension was present, nevertheless similar renal pathologic change was found occasionally in the cases in which blood pressure was normal. It would seem that certain systemic factors exist in one individual which cause hypertension in the presence of a renal lesion but that existence of the same factors does not affect the blood pressure of another individual. It is of interest that, of ten patients with hypertensive atrophic pyelonephritis, seven were females. In contrast to the high incidence of hypertension in association with atrophic pyelonephritis, the blood pressure was normal in five cases in which operation was performed for congenital hypoplasia.

Knowledge of the postoperative course of the blood pressure was available through follow-up records in eighteen of the forty-three cases of atrophic pyelonephritis. In this group of eighteen patients were ten who had had hypertension preoperatively and it was found that the blood pressure of seven of these had returned to normal after operation, while it was not influenced in three cases. Of the eight cases in which the blood pressure had been normal preoperatively hypertension developed after operation in one, while it remained normal in the others. It was difficult to determine, on preoperative clinical examination, whether

Renal Stone.—A review of the blood pressure in 793 cases in which operation was performed for renal stone (hydronephrosis with stone, stone with infection and stone without infection) revealed that there were 161 cases, or 20.3 per cent, in which the blood pressure was 145 mm. or more. Although the statistical incidence

of hypertension in association with renal stone did not differ much from the percentage in all cases, the actual incidence of hypertension in association with stone is slightly higher than this survey indicated, because among the patients with stone was a somewhat larger percentage less than 50 years of age. The influence of secondary infection on the blood pressure in cases of stone is shown by the fact that hypertension occurred in 22.5 per cent of cases in which there was manifest infection and in only 5.7 per cent of cases in which there was little or no infection. The degree of pyuria was not the important factor; neither was the reduction in function or urographic deformity of the affected kidney; the extent of atrophic changes in the renal parenchyma and the vascular sclerosis apparently caused the hypertension. It should be noted that in eight, or 40.0 per cent, of the twenty cases of atrophic pyelonephritis associated with hypertension renal lithiasis existed previous to the other conditions. It may be inferred, therefore, that renal stone with atrophic types of infection is a factor in causing renal hypertension. The incidence of hypertension in cases of bilateral stone was found to be no greater than in cases of unilateral stone.

The postoperative course was traced in 189 cases of renal stone. Of this number, in 111 cases hypertension had been present preoperatively and in seventy-eight cases preoperative blood pressure had been normal. The group of 111 cases in which hypertension had been present preoperatively was divided into (1) twenty-five cases in which the blood pressure returned to normal following operation, (2) ten cases in which the blood pressure returned to normal for a variable period after operation but subsequently became elevated and (3) seventy-six cases in which the blood pressure was not altered by surgical measures. It is of interest that the blood pressure returned to normal and remained normal following surgical intervention in approximately 23 per cent of the cases in which hypertension had been present preoperatively. Although nephrectomy was carried out in most of these cases, the blood pressure became normal in many cases following nephrolithotomy. It may be assumed that removal of an irritating and blocking stone

nephrectomy would cause reduction in blood pressure. A comparatively recent onset of hypertension, and a short duration of symptoms, with no hypertensive changes in other tissues, seemed to warrant the best prognosis. The percentage of cases in which blood pressure was permanently reduced after nephrectomy for atrophic pyelonephritis (70) was far greater than when nephrectomy was performed for any other type of lesion.

and drainage of infected portions could remove factors which influenced hypertension. In the ten cases mentioned previously the blood pressure returned to normal after operation and remained normal over a period of from six months to two years, but subsequently hypertension returned. Apparently etiologic factors of hypertension may be temporarily allayed by operation, but other underlying systemic factors may reassert themselves subsequently.

It is evident that etiologic factors other than those relative to the kidney were present in the group of seventy-six cases in which hypertension was not affected by operation. In the majority of these cases the renal lesion was unilateral and the failure in reduction of blood pressure could not be explained by any lesion in the other kidney, at least as far as could be determined on careful examination. Although many cases in which nephrectomy was performed were included in this group, in most of the cases a conservative operation had been performed.

Hypertension developed subsequent to operation in twelve cases in which the preoperative blood pressure had been normal. In ten of these cases the increase in blood pressure followed a conservative renal operation. In this group were several cases in which the blood pressure returned to normal following secondary nephrectomy. It can be assumed, therefore, that when hypertension develops following nephrolithotomy the possible development of postoperative nephrosclerosis must be considered and subsequent nephrectomy may be advisable.

Hydronephrosis.—The low incidence of hypertension accompanying hydronephrosis without stone (table 2) can be explained partially by the large number of patients in this group who were less than 50 years of age. Hypertension afflicted only 7.7 per cent of the patients less than 50 years of age and 38.9 per cent of the patients more than 50 years of age. The size of the hydronephrotic sac and the degree of stasis were not a factor, since there was no difference in the incidence of hypertension in the presence of hydronephrosis graded 1 or 2 taken together and in the presence of that graded 4 or more. Bilateral hydronephrosis, which occurs often, was not accompanied by hypertension except in two cases in which bilateral hydronephrosis and acute renal stasis were present. The presence of infection was not in itself an important factor in the presence of hydronephrosis, since the incidence of hypertension in cases in which infection was present was only 14.3 per cent. As was true in the cases of stone and pyelonephritis, the resulting sclerotic and atrophic changes in the renal parenchyma were the deciding factors.

The postoperative course of seventy-three patients operated on for hydronephrosis without stone was traced. Of this number, twenty-nine had had hypertension preoperatively. In forty-two cases the preoperative blood pressure had been normal and remained so and in two other cases, although the preoperative blood pressure had been normal, hypertension developed after operation. Among the twenty-nine cases in which hypertension had been present preoperatively there were ten, or 34.4 per cent, in which the blood pressure returned to normal following surgical measures and remained normal for from one to five years. Nephrectomy was performed in eight of these ten cases and conservative operation in two. The hypertension

persisted in sixteen of the twenty-nine cases in spite of nephrectomy and apparently was not related to renal pathologic change. Although hydronephrosis was bilateral in four of these cases, this did not seem to be etiologic of hypertension, since surgical drainage did not affect it and the function of the two kidneys, taken together, was normal.

Renal Tuberculosis.—In a group of 158 patients operated on for renal tuberculosis hypertension was found in only twelve cases, or 7.6 per cent. Although one might expect a high incidence of hypertension with diffuse tuberculous infection of the kidney, which is often of a cicatricial nature, the contrary was true (table 2). Nephrosclerosis may be present but vascular sclerosis is apparently uncommon in the presence of the renal pathologic changes which occur with tuberculosis. In explaining the low incidence of hypertension the factor of age is of importance, since 132 patients, or 83.5 per cent, were less than 50 years of age.

Hypertension might be expected to occur as a result of the extensive atrophic changes which take place in the tuberculous kidney which has undergone so-called autonephrectomy. However, of a group of thirty-seven cases in which autonephrectomy was diagnosed, hypertension occurred in only five, or 13.5 per cent. There was no increase in the incidence of hypertension among the patients with bilateral renal involvement.

The course of hypertension following nephrectomy for renal tuberculosis is of interest. Eleven patients were traced who had had preoperative hypertension with renal tuberculosis. Of this number the blood pressure of seven returned to normal. The blood pressure of two others remained normal for less than a year and subsequently became elevated. In the two remaining cases the hypertension was not influenced by nephrectomy. It is evident that, although the incidence of hypertension with renal tuberculosis is low, the chance for recovery following nephrectomy is encouraging.

Renal Tumor.—It is evident that the factor of age explains the comparatively high incidence of hypertension in this group (table 2) since eighty-seven, or 63.5 per cent, of these patients were 50 years of age or more. It should also be stated that the blood pressure in most cases was elevated only moderately, since it was below 160 mm. in nineteen, or 50 per cent, of the thirty-eight cases. The possibility of a pressor substance being secreted or of secretion of such a substance being stimulated by the tumor cells has been suggested by several observers and must be considered. Against this hypothesis, however, is the negative evidence obtained by Bradley and Pincoffs³ by means of perfusates in several cases of Wilms's tumor. The large number of patients with hypernephroma whose blood pressure is not elevated would tend to negate the hypothesis of pressor secretion. Secondary renal infection may have some effect on blood pressure, although hypertension was present in only four of twelve cases in which infection was a factor.

There are not enough cases of renal neoplasm other than hypernephroma to allow an accurate survey of each type to be made. Hypertension was noted in six cases of epithelioma of the renal pelvis and the blood pressure returned to normal after nephrectomy in only

3. Bradley, J. E., and Pincoffs, M. C.: Association of Adenomyosarcoma of Kidney (Wilms Tumor) with Arterial Hypertension, *Ann. Int. Med.* 11: 1613-1628 (March) 1938.

one case. The blood pressure was recorded in eighteen cases of Wilms's tumor and definite hypertension was noted in only five.

The postoperative course of forty-three patients operated on for hypernephroma was traced. Preoperative hypertension had been present in twenty-one of these cases. The blood pressure returned to normal after nephrectomy in nine of them; in three of the cases there was a temporary drop in blood pressure, with subsequent hypertension. The hypertension was not affected by nephrectomy in nine of the cases and it could be assumed that extrarenal factors caused the hypertension in this group and that the presence of the tumor was merely coincidental.

Of particular interest was a case of polycystic disease with hypertension in which one kidney had become functionless as a result of diffuse infection. The blood pressure returned to normal following nephrectomy and had remained normal for more than a year when the most recent information was obtained. In another case of polycystic disease, wherein a similar condition was present, blood pressure was temporarily reduced but in a few months hypertension returned.

POSTOPERATIVE HYPERTENSION

The blood pressure of fourteen patients was normal prior to a conservative renal operation, and hypertension developed after the operation. Urologic examination revealed evidence of reduced function and persistent infection in the kidney subjected to previous operation and, after removal of the kidney, the blood pressure became normal. Examination of the removed kidney usually disclosed widespread tissue atrophy and vascular sclerosis, which apparently had resulted from operative trauma and infection. The operations that were performed, or the conditions for which operations were performed, were, as far as we could learn, nephrolithiasis, hydronephrosis, nephrostomy, ureterolithotomy, nephropexy, ureterovaginal fistula following hysterectomy and persistent vaginal fistula. Nephrosclerosis as a cause of hypertension was observed in two cases following severe renal injury. In every case of hypertension in which there was a history of previous renal operation or renal injury, therefore, the possibility of postoperative nephrosclerosis must be considered.

A postoperative increase in blood pressure apparently occurs more frequently following conservative operation for renal and ureteral lithiasis than other lesions. In considering the advisability of nephrectomy in the presence of renal stone and extensive infection, the possibility of subsequent development of sclerotic pyelonephritis with hypertension must be borne in mind. Postoperative renal atrophy and sclerosis may also explain the hypertension which sometimes is observed following transplantation of the ureters into the sigmoid. Postoperative urographic examination in two of these cases revealed that one kidney was functionless and exploration of the affected kidney disclosed widespread sclerotic changes as the result of infection and stasis. Removal of the affected kidney was followed by restoration of the blood pressure to normal.

RENAL INSUFFICIENCY

Renal insufficiency was not found to be etiologic of hypertension in the cases in which renal surgical operation was performed. In cases in which bilateral stone and hydronephrosis were present, together with moderate impairment of function of both kidneys, and in which both kidneys were subjected to conservative operation,

the incidence of hypertension was not greater than in similar cases in which function was not impaired. Among patients with insufficiency of both kidneys, who were examined but not operated on because of low renal function, the incidence of hypertension was only a trifle higher than in the random group.

RENAL BACK PRESSURE

Renal back pressure is not of much significance in causing hypertension. The average blood pressure in cases in which the hydronephrotic sac was large or in cases of bilateral hydronephrosis was no higher than normal. Hypertension developed in two cases of bilateral hydronephrosis in which one kidney suddenly became occluded and it was relieved in one of these cases by renal drainage.

CONTRAINDICATIONS TO SURGICAL INTERVENTION

Hypertension is caused by factors other than those relative to the kidney in most cases and the presence of a surgical kidney may be of only coincidental clinical significance. This is proved by the large number of cases in which hypertension is present but there is no reduction in blood pressure following removal of a diseased kidney. Nephrectomy may be contraindicated in cases in which hypertension accompanies a surgical renal lesion if any of the following factors are present: (1) bilateral renal disease so extensive that removal of one kidney would be of no benefit; (2) the existence of hypertension of long standing, with such extensive secondary degenerative lesions in other organs that removal of a diseased kidney would no longer influence the subsequent clinical course; (3) evidence of advanced renal insufficiency, and (4) existence, in another organ, of an unrelated serious lesion which in itself might be regarded as inoperable.

COURSE OF BLOOD PRESSURE AFTER OPERATION

The postoperative course of the blood pressure was followed in 372 cases in which surgical operation was performed on the kidney. All these patients were traced for at least six months, the majority of them for more than a year and, in several instances, for as long as five years. Preoperative hypertension had been observed in 198 of these cases and the preoperative blood pressure had been normal in 174 cases. Hypertension was permanently relieved by surgical operation for various renal lesions in sixty-five, or approximately a third, of the 198 cases. Hypertension in the presence of surgical lesions of the kidney was relieved more often by nephrectomy than by conservative operation.

In seventeen cases there was a postoperative drop in blood pressure but the hypertension returned within a few weeks or months following operation. A temporary drop in blood pressure, occurring immediately after operation, often is caused by rest in bed and removal of a toxic irritant. In several cases the blood pressure remained normal as long as two years after operation and then returned to the preoperative level. In such cases it may be inferred that primary hypertension existed and had been temporarily increased by a surgical renal lesion. In order to determine the permanent result of the operation it is necessary to follow the patient's blood pressure for at least two years. There were 117 cases in which alteration in blood pressure did not take place as a result of surgical operation on the kidney. Since evidence of disease of the other kidney could not be determined by careful examination, it would be logical to assume that all these

patients were suffering from so-called essential hypertension and that their condition was not influenced by a renal pathologic condition, at least of a surgical nature. Included in this group were seventy-two cases in which nephrectomy was performed and forty-five in which the operation was conservative. Among the cases in which preoperative blood pressure was normal, hypertension developed subsequent to operation in twenty. Several cases were included in this group in which the increased blood pressure was caused by postoperative nephrosclerosis and in which subsequent nephrectomy caused the blood pressure to return to normal.

COMMENT AND SUMMARY

Hypertension occurring in the presence of a unilateral lesion of the kidney was frequently relieved by surgical operation on the kidney.

The incidence of hypertension in a group of 1,684 patients subjected to renal surgical operation was no higher than it was in a group of patients taken at random. In a study of the incidence of hypertension the factor of age is of importance.

The renal lesion amenable to surgical treatment which occurs most often in association with hypertension is atrophic pyelonephritis. This lesion is the result of extensive infection and is characterized by widespread atrophy of the renal tissues and sclerosis of the renal blood vessels; apparently this process causes hypertension. Hypertension afflicted twenty of forty-three patients operated on for primary atrophic pyelonephritis, or 46.5 per cent. The incidence of hypertension is low in cases in which operation is performed for pyelonephritis without atrophy and sclerosis. Acute cortical renal infection or perinephric abscess is seldom a factor in causing hypertension.

Hypertension was observed in 161 cases, or 20.3 per cent, of 793 cases in which operation was performed for renal stone. The role of secondary infection is important, since hypertension occurred in 22.5 per cent of cases in which infection was manifest and in only 5.7 per cent of cases in which there was no infection. However, the deciding factor was not the degree of infection but the presence of extensive vascular sclerosis and parenchymal atrophy.

Hypertension was noted in approximately 14 per cent of cases of hydronephrosis without stone for which operation was performed. As with renal stone, the presence of tissue atrophy and vascular sclerosis seemed to affect the blood pressure. The degree of pyelectasis did not seem to be a factor, since the incidence of hypertension was no greater in cases in which pyelectasis was of grade 4 than in cases in which it was of grade 1.

Hypertension was observed less frequently in the presence of renal tuberculosis than as an accompaniment of most other forms of surgical kidney. It was present in twelve, or 7.6 per cent, of the 158 cases of renal tuberculosis studied.

Hypertension was found in thirty-eight cases, or 27.7 per cent, of 137 cases in which operation was performed for renal adenocarcinoma. The comparatively high incidence of hypertension in this group of cases is increased by the factor of age, since eighty-seven patients, or 63.5 per cent, were in the sixth decade of life or older. The exact influence of the neoplasm is obscure; the secretion of a pressor substance has been surmised, but corroboratory chemical and physiologic evidence is wanting.

Hypertension may develop in a variable time after a previous conservative renal operation. In many of these cases the blood pressure becomes normal after removal of the affected kidney. In every case of hypertension in which there is a history of previous operation, the possibility of postoperative nephrosclerosis must be considered.

Renal insufficiency apparently is not a factor in causing hypertension. In most cases of hypertension no evidence of reduced renal function was found. On the other hand, many patients whose renal function was reduced had no hypertension.

Back pressure as the result of renal stasis usually is not a factor in hypertension unless acute bilateral obstruction is present.

The discovery of a unilateral renal lesion in the presence of hypertension does not indicate that operation is advisable in every case, since other factors are often present which would contraindicate it.

Bilateral renal involvement, such as occurred in many cases of renal stone, hydronephrosis and renal tuberculosis, was not an etiologic factor in hypertension.

A follow-up study was made in 198 cases in which hypertension was present and in which surgical operation was performed. The blood pressure became normal after operation in sixty-five, or a third, of the cases and remained normal for a year or more.

It may be predicated that hypertension will be relieved by surgical operation in approximately 70 per cent of cases in which it accompanies atrophic pyelonephritis, in 50 per cent of cases in which it is associated with renal tuberculosis and in 25 per cent of cases in which it is an accompaniment of renal stone, hydronephrosis or tumor.

Although hypertension which is associated with surgical lesions of the kidney is relieved more often by nephrectomy than by conservative operation, the blood pressure often returned to normal after nephrolithotomy and renal drainage.

Reduction in blood pressure may exist as long as a year or more after operation and yet hypertension may return. This may be explained on the ground that a toxic or irritant lesion has been eliminated and, when this influence has worn off, the underlying essential hypertension reasserts itself. In order to determine whether recovery after operation is permanent it is necessary to determine the patient's blood pressure for more than a year.

Hookworm.—Hookworm disease in the United States is due to *Necator americanus* (except in a small area in California). The adult parasite lives in the upper part of the small intestine, where it is attached to the mucosa and sucks blood from the host, so that the essential clinical picture is one of anemia. The degree of clinical symptomatology depends in general on the number of parasites harbored. Ova are discharged in the feces and hatch only on exposure to the air. The larvae live in the soil and pass through several molts until the infective stage is reached. Invasion of the host occurs in practically every instance through the bare skin, usually of the foot. The larvae penetrate to the lymph circulation, thence through the general circulation to the lungs. They pass through the alveoli to the bronchial tree and are carried up to the posterior nasopharynx and swallowed. Once in the small intestine, the adults fasten themselves to the mucosa and are removed with difficulty. They may live for five years or longer.—Smillie, Wilson G.: Public Health Administration in the United States, New York, Macmillan Company, 1940.

VASCULAR NEPHRITIS AND HYPERTENSION

A COMBINED CLINICAL AND CLINICOPATHOLOGIC
STUDY OF 150 NEPHRECTOMIZED PATIENTS

NATHAN CHASET, M.D.

BOSTON

In recent years, medical interest has been centered on the problem of hypertension. Although it was in 1827 that Bright connected the condition of the kidney with blood pressure and there have been frequent observations of the relation of cardiac hypertrophy to surgical renal disease which date back as far as 1835, it remained for Goldblatt's¹ work on experimentally produced hypertension in dogs and monkeys to reawaken interest in the subject and open a new and profitable approach to experimentation.

Renal ischemia may be produced in a variety of ways. In addition to the classic experiments of Goldblatt and the recording of numerous instances of hypertension in polycystic kidneys and hydronephrosis, one must con-

Fig. 1.—Comparison of blood pressure of age groups with "normal." Solid line, 150 nephrectomy cases; broken line, 5,540 cases compiled by Wetherby (average of males and females, Berglund and Medes¹⁰).

sider arteriosclerotic plaques of the renal artery and pyelonephritis as causal factors.

Blackman² examined fifty cases of "essential" hypertension and fifty control cases without hypertension and found arteriosclerotic plaques causing reduction in the lumens of one of each of the main renal arteries in forty-three (86 per cent) of the cases with hypertension. The control cases showed only five (10 per cent) with comparable lesions. It should be accepted that renal ischemia can cause hypertension under certain conditions.

Longcope³ studied the relation of bilateral chronic pyelonephritis to hypertension in cases ending fatally. He concluded that the factor involved in the production of hypertension was not associated with renal failure.

Weiss and Parker⁴ concluded that pyelonephritis is often associated with arterial hypertension and that vas-

cular changes frequently occur. They further concluded that there is a great tendency toward severe hypertension in patients with pyelonephritis and that pyelonephritis is responsible for at least 15 to 20 per cent of cases of malignant hypertension. They seem to imply that the sequence of events in pyelonephritis leads to the terminal stage of severe hypertension. With certain reservations in mind, it should be accepted that pyelonephritis causes renal damage which may in turn lead to hypertension. The exact nature of the specific lesion causing hypertension is doubtful at least.

Butler⁵ in 1937, and later Leadbetter and Burkland,⁶ reported cases of unilateral renal disease associated with hypertension in which apparent cure of the hypertension was produced by nephrectomy. Many other observers⁷ soon followed with well studied case reports, and many more will undoubtedly soon be added. These cases have been carefully studied and may be accepted as proved, representing another phase of the problem of hypertension. We must therefore accept the evidence that unilateral renal disease is capable of producing hypertension and that the blood pressure is influenced favorably by elimination of the diseased kidney in some cases.

In spite of these authentic instances, which even now do not comprise a large group of cases, it has appeared to urologists that this association of renal disease with hypertensive cases is not the rule in urologic practice. The challenge to the urologist's concept has been accepted by Crabtree and Prien⁸ and by Mulholland.⁹

It is our purpose in this study to examine, through the specimen obtained by nephrectomy, with respect both to hypertension and to vascular changes in the kidney, a series of routine urologic cases which often represent long standing, severe degrees of unilateral renal damage. Such a study affords a mean of examination of the pathologic processes in the kidney, together with clinical end results of therapy.

One hundred and fifty almost consecutive nephrectomized patients were studied urologically and by pathologic examinations of the removed kidneys. The pathologic studies were detailed, in that examinations of the more normal portions of the kidneys were made as well as of the grosser aspects of the lesion present. Special attention was given to the condition of the blood vessels in both the more normal and the more diseased portions of the specimens.

The age, sex and blood pressure of these cases is shown graphically in table 1. These statistics are quite comparable to those compiled by Wetherby¹⁰ in a statistical study of 5,540 normal individuals. The blood pressure determination of any individual was arrived at by study of all known blood pressure readings before

mined by taking the average of the recent readings, excluding the remote pressures. Some of our patients had only one preoperative blood pressure determination, which was usually taken the night before operation.

Fig. 3.—Section of the tubular portion of the same kidney as in figure 2. Note a sclerosed vessel in the right upper portion and hyaline debris in lumens of tubules.

These readings will tend to give our averages a higher value, since excitement and nervousness definitely elevate blood pressure. This has been found to be a factor in many cases which have been followed carefully since the present study was begun.

TABLE 1.—Age, Sex and Blood Pressure

recorded. Despite this, a comparison with the average blood pressures of men and women in Wetherby's study shows the averages of our severe renal damage group

Fig. 4.—Section from the cortical portion of the kidney from a case of chronic pyelonephritis without hypertension. The tufts of the glomeruli are in fairly normal condition but thickening of the peripheral layer of Bowman's capsule characterizes this lesion.

to be somewhat lower. This comparison has been charted in figure 1. A comparison of age group 10-19 has been omitted, since only one case fell into this group. The figures for charting Wetherby's averages were obtained by averaging his readings for men and for women in the same age group. This was necessary, since the groups studied and recorded related to both sexes.

It might be argued that hypertensive cases might be hidden by averaging large groups of individuals. In order to study more in detail the actual presence of hypertension in this series, all cases showing blood pressures above 150 systolic, 100 diastolic, were further investigated. Fourteen cases were found. The age groups, the blood pressure, and the pathologic condition are shown in table 2. Follow-up blood pressure readings were obtained of twelve of these patients and have

11. Alexander, Franz: Psychoanalytic Study of a Case of Essential Hypertension, *Psychosom. Med.* 1: 139 (Jan.) 1939.

been recorded. No follow-up was obtained of the other two patients because they could not be located.

The pathologic conditions found in this survey are shown in table 3. The types of disease and age distribution of this group are strikingly similar to the summary of 180 cases of nephrectomy recently reviewed by

Deming.¹² The age distribution of the neoplastic group is quite consistent with the 642 cases of renal neoplasia studied by Priestley.¹³ The cases here presented may be considered representative of severe unilateral renal damage.

Fig. 5.—Section of pyelonephritic kidney of patient without hypertension. Lesion of grade 3 as defined in text. In figures 5, 6 and 7 note that the lesions occur in the larger arteries of the kidneys and that the sclerosing process involves the circumference of the vessels and that the lumens of the vessels are greatly reduced in size.

The microscopic study of these cases was particularly detailed, with special attention given to inflammatory

and blood vessel changes. Of our 150 cases, ninety-nine (66 per cent) showed chronic renal infection. The degree of damage varied in each case, of course, but all cases showed marked hyalinization and fibrosis of glomeruli in portions or all parts of the specimen.

Fig. 6.—Section of pyelonephritic kidney of patient without hypertension. Lesion of grade 3.

Examples of the glomerular changes are shown in figures 2, 3 and 4. The changes depicted here were common in the majority of this group.

The nature of the influence which marked alteration of glomerular pattern has on the vascular tree is doubtful at the present time. MacCallum¹⁴ has shown that there is an intraglomerular circulatory readjustment of

the vascular pattern, with normally occurring pathologically changed glomeruli in mammals other than man. The exact changes which he described may not apply to man, but it seems safe to assume that some change definitely takes place. Our interest here was not primarily with the pattern of the change but rather with the degree of narrowing of vessel lumens. On a purely arbitrary basis we have classified the vessel changes into three categories, first degree representing small but definite narrowing of the lumen and third degree

representing marked narrowing, almost to the point of complete occlusion, with second degree representing the intermediate changes. Examples of third degree occlusion are shown in figures 5, 6 and 7, second degree in figure 8 and first degree in figure 9. We realize fully that we have no yardstick or exact measurements by which an accurate estimate of arterial occlusion can

TABLE 4.—Renal Vessel Changes

Pathologic Condition	Total Cases	Number Percentage of Cases Showing Renal Vessel Changes		Degree of Vessel Damage		
		Vessel Changes	Showing Renal Vessel Changes	1°	2°	3°

Of 150 cases, 99 (66%) showed renal infection.
Of 99 cases, 46 (46.4%) showed renal vessel changes.
Of 58 cases with vessel changes, 46 (79.3%) showed renal infection.

be determined in this present study. We do believe, however, that narrowing to the degree shown in these illustrations may well produce ischemia. All pathologic sections used in illustration are from cases without hypertension.

The changes in renal vessels in our study are shown in table 4. The tabulated results represent, in each case,

Fig. 7.—Section of pyelonephritic kidney of patient without hypertension. Lesion of grade 3.

an evaluation of the stages of the pathologic processes which occur in the kidneys. The degree of narrowing is not determined by the condition of a single isolated vessel. On the whole it was found to be the rule that, if the vessels of the most damaged portions of the kidneys were changed, some degree of change was

present throughout the whole of the kidney. No portion of such kidneys from which sections were taken appeared to have normal vessels. We have classified the kidneys on the vascular condition of the vessels in the major proportion of the kidney. In all, approxi-

Fig. 8.—Grade 2 lesion as described in the text. Note that the vessel wall change is confined to but a portion of the circumference of the vessel.

mately 1,500 pathologic sections were examined. In the entire group, fifty-eight cases showed definite renal vessel changes. In the infectious group, which represented 66 per cent of the total group, we found forty-six (79 per cent) of the vessel changes. The group of chronic pyelonephritis with hydronephrosis showed that approximately 50 per cent had renal vessel changes.

COMMENT

We have attempted to evaluate the hypertensive tendency in 150 cases representing severe unilateral renal damage. Hypertension is not characteristic of these cases. A comparison with average blood pressure readings for the age groups indicates that our cases average slightly lower than normal. The possibility that a hypertensive tendency might be hidden by averaging large groups has been considered. In table 2, all cases showing hypertension have been reviewed. Only fourteen cases showed hypertension. Six of these were hypernephroma, seven chronic pyelonephritis and one tuberculous pyelonephritis. The cases showing the severest hypertension occurred in hypernephroma, in which the age often was in the higher brackets.

The follow-up study on those cases which showed hypertension failed to show any definite trend toward improvement in blood pressure readings after nephrectomy. Two cases showed slight improvement; one hypernephroma and one chronic pyelonephritis. In two cases there was no follow-up.

An attempt to correlate hypertension and renal vessel change also met with failure. Again we recognize that our method of study furnishes no basis for estimating the production of renal ischemia. The total number of cases which showed hypertension is far too few in comparison with the large number which showed renal vessel changes to establish a sufficient correlation to

indicate that renal biopsy is a worthwhile diagnostic measure. Three of our cases of hypertension showed no alteration in renal vessels.

SUMMARY AND CONCLUSIONS

1. One hundred and fifty approximately consecutive nephrectomies were studied. These cases were representative of severe unilateral renal damage.

2. Hypertension was not a common finding in the clinical picture in this group.

3. Vascular changes, which have been considered to be causative factors in the production of hypertension, were present in a high percentage of our cases.

4. Elevation of blood pressure readings was not the rule, even in chronic pyelonephritis, in these cases. Nephrectomy was not followed by appreciable reduction in blood pressure readings before operation.

5. The exact etiologic factor in renal (ischemic) hypertension is as yet unknown. The pathologic and anatomic elements seem less important than an as yet unknown physiologic element.

Fig. 9.—Grade 1 changes in an artery of a pyelonephritic kidney. Note that there is uniform change throughout the circumference of the vessel but that the lumen is not extensively narrowed.

6. Evidence is not produced by this study to encourage employment of nephrectomy in hypertensive cases, except for recognized surgical indications.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BRAASCH, WALTERS AND HAMMER
AND DRS. CRABTREE AND CHASET

DR. STANFORD W. MULHOLLAND, Philadelphia: A year ago I was interested in experimental work regarding interference with the circulation to the kidney. I was reading isolated reports by surgeons who had found that certain of their patients with single kidney involvement would have diminution in their blood pressure following unilateral nephrectomy. It was necessary to go back and look at the cases in which I had operated previously with extensive kidney damage in order to correlate the experimental work. Dr. Braasch and Dr. Crabtree have reviewed large numbers of cases and have given interesting facts. The work they have done helps to make one realize that the problem is still physiologic. It is still a problem in which one must be looking for the element that is the underlying principle producing the result: the hypertension. Infection, malposition and stone causes blood vessel changes but the result is not always the same. Longcope has summarized our present knowledge of this mystery. He reminds us that no one has been able to tell why one patient develops hyper-

tension long before there is any evidence of renal insufficiency and another patient develops hypertension only after there has been marked renal damage, while at the same time a third patient may die of uremia without having any hypertension. Physiologists have called attention to the fact that a preponderance of the work done by the kidney is accomplished by tubular excretion. It has been found that a comparatively small amount of the work is done by glomerular filtration. Perhaps it is the variation in the degree of damage to the real working renal mechanism that causes the development of this picture we know so well. It is an open challenge to be looking out for these cases that might fall into the group that will be aided by operation. We in Philadelphia are still reviewing our cases with the idea of trying to locate the influencing factor.

DR. ROY J. HOLMES, Miami, Fla.: The observation of Drs. Braasch, Walters and Hammer that atrophic pyelonephritis is the only type of surgical renal lesion associated with hypertension which can be removed with a degree of confidence is in keeping with my own experience. Renal anemia from defective arterial development is a possible factor and may manifest itself only by a reduction in the number of normal renal units and in the rate of renal blood flow. In studying the blood supply in two cases it appears to me that acquired atrophic pyelonephritis may readily be confused with congenital partial hypoplasia or anemia, on which a mild infection may or may not have been superimposed. Abnormalities and extreme variations of the renal artery are very common. In the two families I have known in which almost every member suffered from hypertension at an early age, the percentage of renal deaths seemed to be unusually high. It is pure speculation to suggest that this may throw some light on the well known familial or hereditary tendencies in some cases of hypertension. I am convinced that a kidney not already a legitimate candidate for nephrectomy should be sacrificed only if the kidney under suspicion is markedly reduced in size as compared with its normal fellow. The paper of Drs. Crabtree and Chaset is a much needed contribution tending to clarify the relation between the field of surgical renal pathology and hypertension and possibly directing attention more to renal anemia in which hyalinization, thickening of the arterioles and even functional impairment are secondary, not primary, factors. That degenerative changes are not always the measurement of renal ischemia is illustrated by many of Goldblatt's experiments in which little if any changes could be found in the renal unit or in its functional ability. Since endeavoring to institute methods of estimating the physiologically effective rate of renal blood flow, I feel that this, together with an accurate estimation of the size of the renal excretory mass, may give a faint answer to the challenge which, as Drs. Crabtree and Chaset say, still exists. We are indebted to Drs. Crabtree and Chaset for showing us that hypertension is rarely found in candidates for nephrectomy. We can, however, find considerable reward and encouragement by looking for small unilateral sclerotic kidneys with little if any urinary symptoms in hopeless victims of essential hypertension.

DR. EARL E. EWERT, Boston: Such papers as these will help form a standard in governing one's action toward patients suffering with various types of unilateral disease. Most of us are here in order to crystallize our attitude. In short, we are afraid on the one hand to allow patients with unilateral lesions and hypertension to go on if help can be given and, on the other hand, we wish to avoid unnecessary surgery. I think that if we come down to the crux of the situation, this is our attitude.

DR. JAMES F. McCAHEY, Philadelphia: Skepticism about a connection between the kidneys and hypertension has been engendered by what the authors have called "enthusiastic" reports. Nevertheless, such a relationship is suggested by recent experimental and clinical observations which appear to be sound. The experimental evidence has been furnished chiefly by Goldblatt. Page has described another interesting form of experimental hypertension. He found that, if the kidneys of dogs are surrounded with cellophane or silk, a fibrous hull is formed and hypertension follows. Removal of the hull causes a return of the blood pressure to normal. Performing this

procedure on one kidney only causes a moderate elevation of the blood pressure. It is evident that hypertension in human beings differs in important essentials from the experimental form. It seems established that narrowing of the lumen of one renal artery may cause sustained hypertension with serious sequelae. Nephrectomy may be beneficial. Cases of this kind are unusual and an accurate diagnosis is hardly ever possible prior to operation. Therefore, the pressing problem here is for improvement in method of recognizing cases belonging to this category. It is also evident that the disease which we call "essential hypertension" is not a surgical renal consequence. The finding by Drs. Crabtree and Chaset that vascular occlusive changes may be present in the kidney without hypertension is in accord with the opinion of Fishberg, who believes that the essential pathologic condition is generalized arteriosclerosis. Drs. Braasch, Walters and Hammer find that conservative treatment of various surgical renal lesions will often result in a lowering of the blood pressure in patients with a higher than normal reading. They report certain instances of surgical renal conditions associated with hypertension in which the blood pressure did not fall to normal after nephrectomy and interpret this as indicating that the cause of the hypertension was extrarenal. However, the possibilities that the increased vascular pressure depended on a lesion in the opposite kidney must be kept in mind, since the fact that a kidney responds normally to our present tests does not mean that it does not contain arteriolar changes which lead to some degree of hypertension. The onset of such changes in the remaining kidney may likewise explain the occurrence of hypertension some time after nephrectomy. Both papers are in agreement that nephrectomy for hypertension is indicated only in recognized renal surgical conditions. In the present state of our knowledge, this is sound policy.

DR. GEORGE W. FISH, New York: The excellent papers by Dr. Braasch and Dr. Crabtree and their collaborators form a basis for the surgical treatment of certain cases of hypertension. Both workers have arrived at essentially the same conclusions and their methods of selecting cases are marked by a fine conservatism. During the past three years, Schroeder and I have studied and done nephrectomy in a group of hypertensive patients from 16 to 32 years of age with unilateral renal lesions, at least as far as we were able to establish such a diagnosis by intravenous and retrograde urography, separate phenol red and urea clearance determinations of the kidney, and cultures of separated ureteral specimens. Even with all these tests the presence of bilateral lesions is not always ruled out. Perhaps most important of all, the time of the onset of hypertension in these cases was known, and those whose hypertension did not extend beyond two years responded most favorably. These cases were reported in the May 1940 issue of the *American Journal of the Medical Sciences*. These points and the one made by Drs. Crabtree and Chaset concerning biopsy for diagnostic purposes are brought out by a recent case: A white man aged 40 had a stone removed from the right kidney through a pyelotomy incision in February 1937; the blood pressure was 130 systolic, 90 diastolic. In August 1937 the blood pressure was 148 systolic, 100 diastolic. Two attacks of pyelitis on the right side occurred between that date and April 1939; the blood pressure was 165 systolic, 120 diastolic. I saw the patient first in October 1939; the blood pressure ranged from 212 systolic, 140 diastolic to 154 systolic, 100 diastolic. The symptoms were headaches and lassitude. Three months' observation revealed that both kidneys were functionally normal as determined by the phenolsulfonphthalein and urea clearance tests. The right kidney had some pus and colon bacilli. The left kidney was normal. Increase occurred in hypertension and the size of the heart during the observation period. Right nephrectomy was done Jan. 28, 1939. Marked fall of blood pressure occurred to normal levels. Death occurred on the nineteenth day after operation of pulmonary embolus. This and other reported cases and experimental work suggest that the sclerosis described by Dr. Braasch and his collaborators may not be the cause of the hypertension and that the hypertension may be the cause of the sclerosis. Nephrectomy may prove of benefit but, it seems, only for patients in whom the existence of hypertension is of short duration and in whom

arteriolar sclerosis of the other kidney is not advanced. Its use is probably limited therefore to a small number of hypertensive patients and they remain potentially hypertensive.

DR. WILLIAM F. BRAASCH, Rochester, Minn.: One lantern slide which I did not show contained detailed information concerning the group of fourteen patients who had previously been operated on and who developed postoperative hypertension. Injury to the ureters or kidneys occurred in the course of hysterectomy, various other operations for pelvic disease, vesicovaginal fistulas, nephropexy, ureterolithotomy and nephrolithotomy. In one case, which is of particular interest, both ureters had been transplanted into the rectum and several years afterward hypertension developed. One kidney was infected and atrophic and after its removal the blood pressure returned to normal. It may be inferred, therefore, that when hypertension develops after operations involving the urinary tract the possibility of postoperative nephrosclerosis must be considered. Although the incidence of hypertension caused by unilateral surgical renal lesions is relatively low, nevertheless the more one looks for such cases the more often will one find them. It is a condition which the urologist may not see primarily because the urinary symptoms and signs are often obscure. The patient usually comes first to the internist, who often is not on the lookout for surgical renal lesions unless he is familiar with this possibility. This was well illustrated recently by a patient who came to the Mayo Clinic because of headache. The internist who examined him found hypertension, and although only an occasional pus cell was found in the urine he included roentgenography of the urinary tract among the routine diagnostic procedures. The roentgenogram was reported to be negative. The internist, however, was on the lookout for the possibility of renal disease as the cause of hypertension, so he reviewed the roentgenogram himself and saw that the outline of one kidney was definitely smaller than the other. Then he called in the urologist, who also found the difference in renal outlines and suggested that an excretory urogram be made. The urogram visualized deformity typical of atrophic pyelonephritis in one kidney and showed that the other kidney was normal. Nephrectomy was advised and the blood pressure returned to normal subsequently. This field offers the urologist one of the most promising opportunities for clinical investigation. Judging from the statistics I have shown, there can be no doubt as to the efficacy of renal surgery in reduction of blood pressure in certain carefully selected cases.

DR. NATHAN CHASET, Boston: In our study we have found severe pathologic changes without finding hypertension to any extent. The reason has not been obvious, and we have come to believe that some physiologic or chemical process initiated by the kidney is probably responsible for the production of hypertension in many cases, but that equally potent forces in the body can be marshaled to combat it. The role the kidney plays in the production of hypertension is not clear. The work of Page and his associates is probably nearer the true concept than others presented. It is as follows: Experimentally produced hypertension, either by Goldblatt's method or by the method of Page, is caused by the liberation from the kidney of an enzyme-like substance which is called "renin." Renin alone causes no hypertension. It requires a kinase-like material contained in the protein fraction of plasma and whole blood. It has also been shown that tachyphylaxis to renin develops rather rapidly, owing to exhaustion of renin activator. When tachyphylaxis develops in the presence of excess renin, further addition of renin activator does not restore the pressor effect of renin. It appears that some substance develops which prevents the combination of renin and renin activator. This has been called the antipressor state, or renin inhibitor. The interaction of renin and renin activator yields "angiotonin," a highly active pressor substance. Whereas renin causes tachyphylaxis quickly as the result of depletion of renin activator, angiotonin causes only mild tachyphylaxis after many injections. Angiotonin appears to be an intermediate rather than an end product in the interaction of renin and renin activator. It also requires an activator which differs from renin activator. The mechanisms for the production of tachyphylaxis to renin and angiotonin are interrelated. It seems to be due to the

exhaustion of their respective activators as well as to the development of inhibitors. Thus experimentally it seems that there are potent substances capable of vasoconstriction which are liberated by the kidney under certain conditions. There are also equally potent and effective mechanisms for the prevention of the vasoconstrictor action. Studies on the inhibitor mechanisms are being carried out at the present time.

TREATMENT OF COMPOUND FRACTURES IN WAR

REPORTS OF PRACTICAL EXPERIENCE IN THE
SPANISH CIVIL WAR

LEO ELOESSER, M.D.

SAN FRANCISCO

It was evident to surgeons who took part in the late civil war in Spain that modern warfare was to differ greatly from previous wars and that the difference would be due to advances in the mechanics of transportation and especially to extensive use of aviation. It was apparent that surgeons had much to learn and to unlearn in matters of organization, in evacuation of wounded and also in the treatment of war injuries. Especially noticeable was distrust in chemical antiseptics. Irrigations, Dakin's tubes and the complicated ritual of antiseptics that ornamented military hospitals in 1918 were unused or forgotten. Their place was taken by extensive incisions and plaster of paris splints. Rapid military movements and the need, after the bombing of thickly populated centers, of attending great masses of wounded called more than ever for surgical methods that were rapid and safe and that permitted of prompt evacuation with a minimum of postoperative attention. Trueta has written of these methods in his monograph on the Treatment of War Wounds and Fractures. The interest his manual has aroused is evidence of our concern for military preparedness.

For this reason a few further notes based on experiences gathered during the Spanish Civil War may not be amiss.

Rapidly moving warfare dominated by aviation makes simple surgical methods imperative. The necessity of concealing formations from view from the air and of moving men, wounded and supplies quickly, often under the cover of night, compels economy of materials, space and effort. Supplies and essentials are liable to be scanty or wanting entirely, either because they cannot be brought up or because they have been destroyed. Water, especially hot water, is liable to be short; liquid solutions and glass containers are liable to be spilled or broken. However, one learns to adapt oneself, and as the late Dr. Bethune wrote from China, "I find I can get along and operate as well in a dirty Buddhist temple . . . as in a modern operating room with a thousand accessories." The necessary economy and simplicity may by foresight and preparedness work rather to the advantage than to the disadvantage of the wounded.

PREPARATION

The most satisfactory easily transportable and easily procurable skin disinfectant, both for the surgeon and for the patient, is chlorinated lime.

The surgeon cleans his hands with a cream of chlorinated lime and soda worked well into the skin with a brush. If running hot water is scarce this paste is washed off by having a tiny stream of water trickle

on the hands from an irrigator or a can with a spigot. Cleansing is as thorough as though a much larger stream were used. Following disinfection with lime and soda, alcohol, iodine-alcohol or a mercurial in alcohol acetone solution makes it easier to dry the hands and to put on gloves but is not essential.

The patient is thoroughly shaved, either wet or dry, the hair being removed over the whole area which is subsequently to be encased in plaster. One applies a thick paste of chlorinated lime and soda to the skin of the operative field and removes the paste with moist gauze, working outward from the wound as a center. This really cleans the skin of sweat, mud, dirt and grease; it may then be painted with one of the usual alcoholic antiseptic solutions, iodine or a mercurial.

Draperies should be small, so that the surgeon can keep the field under his eye and watch what unskilled assistance is doing. Large expanses of white sheeting are no guaranty of asepsis but are rather in the way. Four drapes about a yard square clipped or sutured to the skin are enough. The skin edges are further protected by large moist gauze squares. A well constructed metal sacral rest is indispensable; improvisation of boxes and enamel basins is most unsatisfactory, but a fracture table is not essential. Two pairs of small pulleys in the form of a block and tackle arranged overhead with other pulleys fastened to the wall at the foot of the table are just as serviceable and much easier to transport than a heavy fracture table. However, a fracture apparatus such as a Dupuy or Zimmer apparatus makes the placing of Kirschner or Mathews wires easier.

ANESTHESIA

Some form of anesthesia is desirable in which the patient is not entirely unconscious but is able to cooperate to some extent. His cooperation makes transportation to and from the operating room easier and saves work for stretcher bearers, surgeons, orderlies and nurses. Soldiers at the front are notoriously easy to anesthetize; they are usually in good physical condition, not overfed nor alcoholic and, when wounded, are often more or less on the verge of shock, so that a little morphine, a little sedation with barbiturates and a little inhalation anesthesia go a long way toward freeing them of pain.

Thus preparation with morphine plus procaine hydrochloride infiltration around the site of injury is often all that is needed for the accomplishment of a thorough débridement and reduction of a compound fracture.

Plexus anesthesia is very satisfactory for injuries of the upper extremity. Twenty cc. of 1 per cent procaine hydrochloride plus two drops of 1:1,000 epinephrine are injected just above the middle of the clavicle; the needle is pointed toward the spinous process of the first dorsal vertebra. As it strikes the plexus, the man feels a sudden tingling pain in the fingers. One should inject the full amount of procaine solution as soon as this pain is felt, moving the needle about a little to inject the various cords of the plexus. Anesthesia follows almost immediately. If the needle misses the plexus it strikes the first rib; it should be moved about until the plexus is found. If injection is made not squarely into the plexus but around it, anesthesia may take from fifteen to twenty minutes to develop. The interval may be used to attend to other wounded.

For lesser injuries, injection around the site of injury is all that is needed.

A little ethyl chloride inhalation given when all is in readiness is sufficient for the few minutes needed to amputate a mangled arm through the site of fracture;

the man wakes up immediately, may often walk to his bed, travel seated in an ambulance and can be given hot drinks without nausea and vomiting. It is especially important that deep general anesthesia be not used for injuries of the upper extremity, for thoracobrachial plaster of paris is easy to apply if the man is seated but difficult or impossible if he is lying unconscious on a table.

For fractures of the lower extremity, low spinal injection of 100 mg. of procaine hydrochloride dissolved in 3 cc. of spinal fluid injected while the man is seated with one or both legs hanging over the edge of the table produces an ideal anesthesia. The injured man retains the use of his arms and can help balance himself on a pelvic support while plaster is being applied. Evipal or pentothal sodium injected slowly until a light narcosis is reached is satisfactory for men who are shocked or frightened. By injecting the drug slowly, drop by drop, one can maintain a constant light narcotic level. Evipal, however, is not satisfactory in skull injuries with unconsciousness and delirium. It seems to increase the delirium and makes the wounded more unruly.

Ethyl chloride administered by dropping it, not spraying it, on an open face mask is a most satisfactory anesthetic for short maneuvers requiring good relaxation. At the moment when the patient first goes under the anesthetic, when he takes a few deep sighing respirations, the mask should be slightly lifted to allow room for plenty of air. If this is done and sudden inhalation of highly concentrated ethyl chloride vapor is thus avoided, the anesthetic is safe: there is no excitement stage and no struggling, which to wounded with fractures are harmful; relaxation is perfect, and consciousness returns without nausea or vomiting a few minutes after the anesthetic has been stopped. No other inhalation agent seems to meet all requirements for short anesthesia so well. Five minutes is to be regarded as the maximum duration of ethyl chloride anesthesia; if more prolonged narcosis is likely to be needed, ethyl chloride should not be given or anesthesia should be changed to ether. Bulky apparatus, inflammability and the need for expert anesthetists preclude the wide use of gas in advanced hospital formations.

X-RAY EXAMINATION

It is seldom necessary to take an x-ray film of a compound war fracture before débridement. Inspection of the limb before operation and of the fracture during operation usually give the needed information. Foreign bodies and the position of fragments are usually self evident in the course of a proper débridement. It is seldom necessary to take an x-ray film immediately after operation and immobilization if the operation is properly done and splints are properly applied. Radiography at the front is time consuming and cumbersome, fluoroscopy still more so.

The time and place for x-ray examination is at the evacuation hospital and farther back, at a time when fractured bone ends may have slipped or osteomyelitis and sequestration may be demonstrable.

The mobile surgical unit which I headed in Spain was equipped with a good modern portable x-ray apparatus and a dark room included in a mobile unit on wheels. They were not once used. The same was true of other advanced units which I had occasion to observe.

Conceivably radiography and fluoroscopy might be advantageous for chest wounds with suspected intrapleural foreign bodies or for abdominal wounds. It is

questionable, however, whether its limited application in small advanced hospital formations calculated for rapid movement and intense activity justifies the time, weight, bulk and personnel needed for its management.

POSITION ON THE OPERATING TABLE

For injuries involving the front and sides of a limb, the wounded are placed on their back; if both front and back have to be dealt with, the limb is elevated or suspended so that the posterior surface is accessible. The man may also temporarily be placed on his side, but the fracture is likely to be considerably displaced in this position.

The arm may be placed on the operating table at the side of the wounded or laid across the chest; it may be held suspended from a pulley or abducted on an arm board or on a side table. It should be placed in the position in which final reduction is likely to be most easily accomplished and maintained. Draperies should not be so bulky that the fracture may be displaced by their removal; they should allow access to the arm and hand so that slings and pulls may be applied for maintenance of position while the limb is being splinted. The same consideration holds good for fractures of the lower extremity. The patient lies on his back; if the posterior surface of the limb is injured it may be placed in a Böhler frame or held suspended by slings and pulleys to allow access from underneath. In any event slings are best laid under the limb before débridement is begun so the fracture may not be displaced later.

In amputation much blood can be saved and the tourniquet dispensed with if the limb which is to be amputated is suspended vertically upright from an overhead pulley by a clove-hitch passed around the ankle or the wrist. All its venous blood is returned to the circulation in this position, while with a tourniquet, however quickly and efficiently it may be applied, some venous stasis occurs while it is being tightened and the venous blood in the limb is lost.

DÉBRIDEMENT

After everything is properly prepared and in readiness and not before, operation is begun; shaving should be complete, draperies adjusted with a view to their subsequent removal, slings and traction apparatus applied or laid under the limb ready for application; for it should be remembered that after débridement the soft parts and bones are to lie in the position which they are to maintain during healing. It is distressing both to the wounded and to the surgeon to see the limb jostled and moved during the application of retention apparatus, splints and bandages often to an extent that should call for a new débridement before the plaster is finally applied. A tourniquet usually makes accurate inspection and operation easier. It should be used only if it can be rapidly and efficiently put on. It can be kept from slipping down on the limb by a towel clip through the skin or one or two sutures. A pneumatic sleeve is the best tourniquet for the arm, a wide rubber tube or an Esmarch bandage for the thigh.

Everything being in readiness, local, spinal or general anesthesia having been induced, the skin edges are excised in the classic manner, retractors are inserted and held gently but firmly, devitalized muscle, contaminated bone chips, foreign bodies, missiles and pieces of clothing are removed. Special attention is paid to visible shreds of clothing and dirt. The position of the limb on the operating table is likely to differ greatly from that which it had when the missile struck it. Contaminated particles may be dragged up and down from

a line drawn between the wound in the skin and the fracture; soft parts, muscle and fascia may have slid one over the other, occluding the tract. In order to lay all of these recesses wide open, the skin and fascia should be widely incised so that the recesses are not under tension and forcible retraction is not necessary to expose them. If forcible retraction is necessary at the time of débridement, the wound will be under tension later. Wide incisions into skin and fascia are unimportant and can be repaired perfectly; insufficient ones are very important and will determine future loss of the limb, sepsis, spreading osteomyelitis, gas gangrene and phlegmons of the soft parts. If the unimportant superficial structures of the skin and fascia are widely incised, more important deeper structures, muscle and bone, will be spared.

The wound should not be dabbed, rubbed and prodded with gauze sponges. If vessels bleed and it is necessary to use gauze in order to see them, the wound should be firmly compressed with a piece of flat gauze held in the fingers; the gauze should then be slowly rolled back until the bleeding point can be seen and caught with a hemostat. Wiping the wound with gauze makes it bleed more and wipes dirt into its crevices.

Necrotic and contaminated muscle should be excised; severed and contaminated nerve ends may be freshened and brought together with a single fine black silk suture left long and allowed to hang out of the wound if it is thought that suppuration is inevitable, or cut short if it is thought that the wound may heal. Formal accurate perineural nerve suture is rarely indicated.

Severed vessels should be caught and tied. Arterial suture is almost never possible or permissible. A compound fracture with a cold pulseless limb calls for amputation unless exceptional vigilance is possible during the first few days after injury.

Tendons lying in a contaminated area may be allowed to remain if they can be cleaned and covered by clean viable soft parts not under tension. If they are severed, their clean freshened ends may be approximated by a single suture and similarly covered. If it is not possible to cover them they had better be allowed to retract into their sheaths, for if they remain exposed in a wound they will certainly slough. More of them will be saved for secondary suture later if they are allowed to retract.

Open and exposed joints should be similarly covered. If it is possible to sew clean synovia over them without tension, their function may be preserved, but in no case should they be covered by skin sutured under tension.

Entirely loose fragments of bone should be removed. Grossly contaminated bone ends from which the periosteum has been stripped should be removed with the rongeur until clean covered bone appears. Grossly contaminated periosteum should be removed.

If the bone ends hold their position without internal fixation, so much the better. If they tend to slip they may be held by a wire passed through drill holes if it is possible to drill the holes without stripping the periosteum and traumatizing the fracture by dislocating its ends from the wound. Oftener it may be possible to grasp the bone ends and hold them approximated with a towel clip, which should be left in the wound. If its branches cannot be closed, the handles may be tied together with a piece of silk or twine. Only if a bone is widely exposed and will obviously sequestrate is it permissible to use metal plates, which should lie fully exposed in the surface of the wound. Their application in the depths of a wound entails needless trauma and exposure of the bone.

Whether packing should be placed about the fracture depends on the extent and duration of contamination and the completeness of débridement. More or less sequestration will almost certainly ensue if the fracture is surrounded by gauze packs. If it is possible to surround it with soft parts without tension, it may heal without suppuration.

A few sutures are permissible when it seems expedient to cover vulnerable structures—tendons, cartilage, blood vessels—which die when exposed or which it is dangerous to allow to remain so. Such sutures should be of fine 00 or 000 catgut or fine silk (if the operator is incorrigibly silky) and should not create tension. If liberating incisions cannot loosen the parts to be sutured, suture had better be withheld.

If all structures lie perfectly loose and naturally, packing may be omitted. If contamination of the fracture site is such that the wound must be left unclean, it may be better to introduce a pack of iodoform gauze or plain gauze. In any event, it seems, in the light of newer experience, that it may be wise to sprinkle the wound liberally with sulfanilamide powder.

During the whole operation, which frequently it does not take as long to perform as it does to tell about, instruments should be changed or wiped and cleaned constantly with moist gauze. This applies especially to scissor blades and the teeth of tissue forceps. The gauze should be discarded each time, and no sponge or gauze should be introduced into the wound twice. Ample incision into the skin and easy exposure will make débridement, even of extensive wounds, not too time consuming.

SUTURE

After each débridement the question arises "Shall the wound be closed by suture?" The answer is usually like Thackeray's to the young man about to marry: Don't. If the pros and cons are weighed each time, the cons will so outweigh the pros that there will be little doubt what to do. The pros reduce themselves to the advantage of a small linear scar—a negligible advantage. Shortening of time of hospitalization scarcely comes into question, for even though the wound is left open and allowed to granulate it will be closed or may be closed by secondary suture or skin grafting by the time the fracture is consolidated. The cons are overwhelming, for it will rarely be possible, in spite of the promptest and most complete débridement, to assure asepsis in extensive war injuries that warrant the performance of a débridement at all. And if such wounds are closed by skin suture producing even the slightest tension, danger to life and limb is great. In the best of events, if suppuration ensues, hospitalization will be measured in terms of years instead of months. Exception may be permissible in wounds of the hand, wrist and ankle, when the danger of serious sepsis is not great, when the skin can be approximated without tension and when valuable tendons will slough unless they are covered.

The wound is covered with small dressings of sterile gauze and the limb is immobilized for evacuation. In wounds that are likely to bleed, sterile gauze is preferable to Orr's petrolatum pack; wounds covered with petrolatum ooze and bleed much longer than when covered by sterile gauze.

APPLICATION OF PLASTER SPLINTS

The use of plaster of paris may justify a few generalities. In surgery, as in every other art, each material calls for its own technic and what is valid for one medium may not be so for another.

In the United States plaster of paris is used on crinoline or starched gauze bandages; in Spain and France plain unstarched gauze bandages are used. Crinoline plaster bandages have more body and are easier to apply without wrinkles; however, their starch content delays setting and makes it necessary to use rapidly setting plaster of high quality (alabaster or dental plaster) if the cast is to set reasonably quickly. The casts are probably not quite so hard but are tougher than the ones made with unstarched bandages. Plaster on plain unstarched gauze is somewhat more difficult to apply smoothly, especially for those used to starched bandages; however, it sets more quickly without the starch, so that slower plaster of inferior quality can still be used satisfactorily. The casts are harder but more brittle than those with starched bandages; they are likely to be a little thicker. In France and Spain flannel cut to a pattern and immersed in a plaster cream is occasionally used. This is especially useful for jackets, body casts and half body casts (plaster shells). It saves time and trouble when properly applied. For general use when good plaster is available the crinoline bandage is probably preferable; if plaster of a poorer grade, and ordinary commercial plaster such as can be bought at most lime kilns, is all that can be had, unstarched plain coarse mesh gauze bandages are better.

Plaster of paris bandages conform to the shape of the body by being molded to it; they have no elasticity and cannot, like gauze or flannel bandages, be pulled or stretched into shape. Their cohesiveness is great; they will not work or slip or stretch. Every crease and every wrinkle in them becomes petrified when the plaster sets and will cause intolerable pressure if it overlies a bony prominence. To pad plaster with absorbent cotton or some such material is to frustrate the purpose of plaster. It will immobilize imperfectly, for the limb will work up and down in its cotton sheath; it will be more and not less likely to cause pressure sores, for it is impossible to mold it accurately to the limb if it is separated from it by an uneven surface, such as that of cotton padding; and lastly and most important the immobilization due to the plaster sticking to the underlying skin is lost, and traction against muscle pull can be secured only by pressure of the plaster splint against flaring surfaces, such as the knee, the ankle, the dorsum of the foot, the heel and the hand below the wrist, instead of being equally distributed throughout the whole limb, as when plaster is applied directly to the skin.

It is obvious that some way of holding a limb must be devised that will keep it in position while the plaster is being put on. It is equally obvious that unless the limb will hold its position by itself, which it will not often do in fractures, its position cannot be retained by the hands of an assistant, for he must let go each time a turn of bandage or a splint is to come between his hands and the patient's skin. Some form of traction is necessary which can hold its place, at least until the plaster hardens, a metal pin, a bandage or some material that can be incorporated into the splint or retain its position under it. It is obvious again that the hands of an assistant do not meet these requirements. Plaster should be applied with regard for what it can do and what is required of it, and (especially in advanced hospitals where the wounded cannot be kept under observation) with more of an eye to what the next few days, weeks and months may bring than with regard to the needs of the moment.

The limb is kept in position by suspending it or pulling on it with bandages which are greased and are incorporated into the cast but are withdrawn before the man leaves the operating table, for they will cause pressure if allowed to remain. Or at times metal pins may be convenient. The need for these will not be great if unpadded casts are used. Traction should not be too forcible if there has been much loss of osseous substance, for a wide gap between bone ends is likely to lead to nonunion. The perfect relaxation of spinal anesthesia increases the risk of wide distraction.

Dressings should be small, just large enough to prevent plaster of paris from leaking into the open wound; they should be held in place by a few small narrow strips of adhesive and not by a bandage encircling the limb; slings should not be too wide; as much skin as possible should be left uncovered for the plaster of paris to adhere to. Painting the area around the wound with compound tincture of benzoin will prevent acne pustules from old wound secretions and help dressings and plaster to stick to the skin.

The plaster should be applied with due regard for the stresses and strains involving both the fracture and the neighboring joints. Lateral strips are laid on first, a few layers at a time, two or three, not more than four. The fit of the cast depends on the neatness and accuracy of these inner layers. They are molded with the hand to the shape of the limb. Creases and folds are removed by notching the strips or removing a V shaped dart, so that the plaster lies perfectly smooth. A half dozen layers or so are laid on and allowed to set a little; reinforcements are added by using shorter strips at the site of fracture or at the joints or by laying on longer strips folded lengthwise. After these longitudinal strips are hard enough to retain their shape and not buckle or dent, they are held in place by a circular bandage one layer only in thickness; no turns or folds are made in this bandage, but it is cut across and started again as soon as it ceases to run smoothly over the longitudinal strips and the limb. Care should be taken that the layers do not accumulate at the bend of the knee and the elbow. It is just here, where pressure is most likely to be harmful, that several layers of circular bandage are likely to overlap. When additional reinforcement is thought necessary, because the man is unusually robust or heavy or because profuse drainage is likely to wet the cast at the site of fracture or because transportation is likely to be long and hard, metal material may be added, but only after the cast is dry enough to resist pressure. If metal reinforcements are added before the plaster is quite set they will dent it and cause pressure points. Cramer splints (wire ladder splints) are particularly likely to do this. The metal, if rationally applied, need be only light and thin. Strips an inch wide cut from an ordinary tin can are just right. They can be bent and molded by hand to fit the cast accurately. If they do this they are stronger than heavier metal which cannot be accurately applied. They are firmly attached to the surface of the cast with a single layer of circular plaster bandage pulled tight. They are placed at the level of the fracture or over joints so that their width resists bending strain; i. e., two pieces at each side of the knee, three or four pieces around a fractured femur, two pieces laterally for leg fractures. If thin aluminum sheeting is at hand this is to be preferred, being pervious to the x-rays. The cast may be made thin in certain spots so that it can break; e. g., it is desirable to put a few spica turns around the hip and pelvis in high

fractures of the leg, but it is not necessary to immobilize the hip. The cast should be thin at the hip so that it can break here. The ankle should be included in casts for fracture of the femur; but, if the cast is thin at the ankle, motion may be preserved.

Suspension strips and especially hitches about the wrist and ankle must be removed before the man leaves the operating room. If the cast inclines to bend or buckle at the point where it is cut for their removal, reinforcements may be added.

Finally, as long as the wounded can be constantly and carefully watched in the same hospital the circular turns may be allowed to remain; if, however, débridement and immobilization are only preparatory to prompt evacuation, before the man leaves the hospital the circular turn should be slit all the way either up the front or the back of the limb and the cast should be wrapped not too tightly with an ordinary gauze bandage. The cast will be less likely to break if it is thoroughly dry before it is slit, if it is possible to wait twenty-four hours, but it should be slit before the wounded man is evacuated, even though it is not thoroughly dry. In dubious wounds it is better not to wrap the cast but to slit it and leave it open. If this is done there need be little fear of constriction or gangrene.

In fractures of the leg the cast is ordinarily applied with the leg lying flat on the operating table; lateral strips are first laid on, as far posteriorly as possible, they are allowed to set, and the circular bandage is then applied. If the leg lies on a rubber sheet the circular turns can be slid under it without lifting it from the table.

Fractures of the femur are put up with the man placed on a sacral rest, his shoulders supported by a box of equal height; the leg is held suspended from overhead pulleys with the knee slightly flexed; traction is made on the ankle by means of a hitch; another sling about the site of fracture keeps the femur from dishing. In the absence of overhead pulleys and in a pinch the femoral sling and the sling about the knee may be held by an assistant who stands on the table, one foot at each side of the fractured femur, facing the patient's feet. He brings the slings about his neck while his back is a little bent; as he straightens up the slings are tightened and the extremity lifted. A thick cotton pad is placed over the abdomen before the plaster is applied to allow for distention.

Fractures of the arm and forearm are put in plaster with the patient seated, on a stool if possible, on the operating table if not. It is almost impossible to put on a thoracobrachial plaster splint with the man lying on his back; hence the need for avoiding ether or prolonged gas anesthesia. The so-called airplane splint, with the shoulder abducted at 90 degrees, is never used. Such a splint, whether of metal or of plaster, works only when the man is flat on his back; when he is up or has his head raised in bed the weight of the splint causes a valgus angulation of the humerus and produces the deformity it seeks to avoid.¹ If transportation is to be comparatively easy, the arm is put up in 45 degrees abduction or less, with the forearm at right angles to the body in the sagittal plane; the cast should include the chest, both shoulders and the arm to the wrist with a turn or two around the hand, in what is known as the Bastos position, after Bastos, formerly professor of surgery at Madrid, now prisoner in a fascist concentration camp. Care should be taken not to tighten the

turns about the chest; before they are applied the man should be called on to blow his chest up. If he cannot do this the lower part of the chest should be padded. The cast may be reinforced by a stick of wood or a Cramer splint leading from the chest to the elbow. It is not easy to apply and, unless it is fairly heavy, is likely to break at the elbow and no great matter. The weight of the forearm sticking out at right angles to the body tends to twist the whole apparatus outward in order that the arm may drop inward. The projecting forearm makes transportation somewhat awkward; the man is likely to be jostled and bumped unless he is seated, when his knees protect the forearm. If, therefore, evacuation is likely to be troublesome it may be better to let the man carry his arm at his side and his forearm across his chest in a sling. Cotton pads are put under the arm and between the forearm and the chest; the sling, arm, forearm and chest are then encircled with a few layers of plaster of paris applied circularly. This position creates an inward rotation deformity of the lower fragment, but it makes evacuation easier, particularly if the man is to lie recumbent, to walk or to stand. The rotation can be corrected later on reaching the base and a Bastos splint applied in correct position. The man should be tagged to this effect when he is evacuated. Evacuation in a 90 degree abduction splint (airplane splint) is torture to all concerned.

EPIDEMIC MENINGITIS

ARCHIBALD L. HOYNE, M.D.

CHICAGO

In this discussion the term "epidemic meningitis"¹ is applied to all patients suffering from meningococcal infections. It does not include carriers but does embrace instances of meningococcemia whether with or without clinical evidence of meningitis.

The contention is made sometimes that this disease is much more severe in the presence of an epidemic than among sporadic or endemic cases. On the basis of my own experience during a number of years, such a view is not acceptable. It is even quite possible that during an extensive outbreak many patients may suffer from attacks that are not extremely severe. Consequently the case fatality rate may be comparatively low. On the other hand it is not unusual to have admitted to our contagious disease hospitals patients with a fulminating type of infection at a time when there have been few reports of the disease. Under the latter circumstances the fatality rate is generally very high.

The foregoing explanation is descriptive of the situation as it has existed in Chicago. Since 1937 the incidence of epidemic meningitis has not been great compared to the years 1927-1935.² Nevertheless the percentage of severe cases has attained a high level. In this connection I observed several years ago, when serum was given intraspinally, what appeared to be a paradoxical situation. There was a higher death rate

From Cook County (Contagious Disease Department), Municipal Contagious Disease (Chicago Health Department) and Children's Memorial hospitals.

among the patients who were treated early than there was for those who entered the hospital late in the course of the disease. The solution for this occurrence lay in the fact that, as a rule, a prompt diagnosis was established when meningitis was of a fulminating type and as a result treatment, which often proved futile, was

instituted at once. But if the patient suffered less severely and especially if no petechiae were seen, several days often elapsed before a physician was summoned and hospitalization ordered. Perhaps then because of the patient's natural resistance or the type of infecting organism, appropriate measures were successful in bringing about recovery.

Often in the past we feared the outcome for the patient with petechiae. Meningococcemia frequently suggested a fatal prognosis. In many such instances there was little or no rigidity of the neck. Yet even without meningeal signs it was a common practice, and still is in some localities, to make a lumbar puncture and administer specific serum. This procedure was carried out even if the spinal fluid appeared normal and no organisms were found. But after the introduction of serum intrathecally the cell count often increased and meningococci became numerous. The irritative effects³ of the serum caused meningitis to be plainly evident. Stiffness of the neck if not present previously now existed and opisthotonos frequently became pronounced with the repetition of intraspinal treatment. The foreign substance (serum) entering the spinal canal increased the permeability of the meninges, and subsequent withdrawals of spinal fluid fulfilled all expectations for a bacterial meningitis. Then future attention was focused on the contents of the spinal fluid. It seems to me that there is often too much anxiety regarding the spinal fluid while insufficient thought is directed toward the condition of the patient. It is really the patient whom we wish to treat, not his spinal fluid. In 1934 I abandoned all forms of intraspinal treatment and never have had any cause to regret such action.

For several years antedating the introduction of sulfanilamide, the procedure⁴ was as follows: (1) blood for culture from each patient, (2) spinal puncture

deferred for patients with petechiae, (3) diagnostic lumbar puncture for every meningitis patient without petechiae. In each instance an effort was made to estimate the amount of antimeningococcus serum or meningococcus antitoxin that would be required to bring about recovery. Just as with diphtheria antitoxin, dosage was based largely on one's experience. Severity and duration of the disease received primary consideration; age was sometimes a factor. Meningococcus antitoxin was given in doses of from 60,000 units (180 cc.) to 100,000 units (300 cc.). For an infant the smaller dose might suffice. If antimeningococcus serum was selected the dose usually varied from 150 to 300 cc. In either instance the antitoxin or serum was diluted with 10 per cent dextrose in saline solution of at least equal volume but preferably double or more the volume. It is important to have the dextrose in saline solution; otherwise the serum may precipitate. To this mixture from 0.5 to 1 cc. of epinephrine hydrochloride was added. The mixture at body temperature was then ready for administration by the drip method. When this plan is followed the flow should be started very slowly but can soon be increased to at least 60 drops a minute. If there is not marked improvement within twelve hours, the treatment should be repeated. By this method I have given as much as 1,200 cc. of horse serum (antitoxin) within four days and seen the patient make an excellent recovery without complications.

In 1935⁵ for seventy-six consecutive patients with meningococcic meningitis treated at the Cook County Hospital and Municipal Contagious Disease Hospital the fatality rate was 11.8 per cent. All these patients were treated intravenously in the manner described without intraspinal therapy. In another group of fifty-four patients similarly treated the fatality rate was 9.2 per cent and the rate for thirty-six of that number who were 20 years of age and less was only 2.6 per cent. At Children's Memorial Hospital the laboratory

has reported sterile spinal fluids within forty-eight and seventy-two hours following the administration intravenously of large doses of meningococcus antitoxin. In each instance a prior culture had been positive. These results are not cited with the thought that intravenous serum therapy should be used to the exclusion of sulfanilamide. They are presented for the purpose of

emphasizing that those who depend solely on the use of sulfanilamide for the treatment of epidemic meningitis are not injecting an irritative serum into the intrathecal sac. This fact receives scant thought when spectacular results are attained by the administration of sulfanilamide by mouth or subcutaneously. To me

Fig. 1.—Child in coma, petechiae numerous, on April 27, 1938, fourth day of disease.

it is an extremely important factor in sulfanilamide treatment when the drug is given in the customary way. In the contagious disease hospitals in Chicago and at Children's Memorial Hospital, no intraspinal therapy is adopted for any kind of meningitis patients. Eventually, I believe, no one with experience will administer serum intrathecally.

From 1937 to 1939 inclusive ninety-nine meningococcal patients were treated in the contagious disease department of the Cook County Hospital, Chicago. The ages varied from 6 months to 62 years and the total number of deaths was twenty-two, or a fatality rate of 22.2 per cent. These figures include all patients regardless of how soon death occurred following admission. Of the entire group, twenty-seven patients were treated exclusively with meningococcus antitoxin, twenty-two with standard antimeningococcal serum, fifteen with sulfanilamide and two with sulfapyridine. The remainder received various combinations of serum, antitoxin and sulfanilamide. There were only three patients who

Fig. 2.—Close-up of figure 1, showing massive purpuric eruption of legs.

had any intraspinal treatment. Two of these were given this form of therapy prior to admission. All three are included among the deaths. From September 1937 to March 1938 there were twenty-eight consecutive patients without a death. During the same years there were sixteen patients treated without any lumbar punctures. In each instance the diagnosis was confirmed by

blood culture. In the latter group there were two deaths. Patients with meningococcemia and little or no evidence of meningitis sometimes do better when no intrathecal punctures are made. Within the past few years we have treated approximately forty patients in this manner.

Even though the meningococcal patient has both clinical and bacteriologic evidence of meningitis, frequent lumbar punctures for the purpose of drainage are not required. In fact, one's aim should be to make as few punctures as possible. One lumbar puncture when necessary for diagnosis is often sufficient. No permanent benefit is derived by making numerous taps with the object of relieving intracranial pressure. With each

Fig. 3.—Bright appearing baby with petechiae fading on May 4, eleventh day of disease, one week after intravenous treatment.

successive puncture the quantity of spinal fluid withdrawn is likely to be greater unless a block occurs, which is less likely to happen if there has been no intrathecal treatment. Frequent drainage is more apt to promote hydrocephalus than to prevent it. The fewer the punctures, the fewer the hospital days. Most of our patients are well in less than two weeks.

In the accompanying tables 134 meningococcal patients are enumerated. They were divided among three hospitals and for the most part treated in the manner described. The number of lumbar punctures in relation to the recovery rate for the different years is a matter of interest, though not necessarily significant. None of the surviving patients developed any serious complications after treatment was commenced. There was only one recurrent case. This was a man treated exclusively with sulfanilamide and whose recovery had appeared to be complete. None of the patients were given any opiates. Among the 134 patients there

were seventeen 1 year of age or less and only two deaths in this group. There were eleven patients more than 35 years old with three deaths. The fatality rate for all 134 patients was 20.8 per cent.

No detailed description of sulfanilamide treatment seems necessary here. Its great value is unchallenged but in many instances an initial dose of serum or antitoxin intravenously seems well worth while. Intravenous therapy then may be followed by the administration of sulfanilamide orally.

REPORT OF CASE

An example of what may be accomplished without intraspinal therapy is illustrated by the case of V. L., an 8 months old boy:

The baby was admitted to Children's Memorial Hospital on the first day of his illness. A lumbar puncture, which might properly have been omitted, disclosed a clear spinal fluid under normal pressure with a count of 10 cells, mostly lymphocytes. No organisms were seen on smear but the culture was positive for meningococci. The blood culture was also positive, and gram-negative organisms were isolated from lesions in the skin. The temperature ranged between 99 and 106 F. during the first three days. A total of 120,000 units of Ferry's meningococcus antitoxin was given intravenously within the first five days. Small doses of sulfanilamide, from $2\frac{1}{2}$ to 10 grains (0.16-0.65 Gm.) every four hours, were also administered intermittently for twenty days.

A second lumbar puncture was made on the twenty-fourth day of illness. In this instance the spinal fluid was also clear. The cell count was 9 and the culture (at the end of forty-eight hours) was negative. Results of the two lumbar punctures are convincing proof that no intrathecal taps were required.

Photographs taken on the fourth and eleventh days of the disease are indicative of the rapid progress toward recovery after intravenous treatment. There were no complications other than scarring at the sites of the cutaneous lesions.

SUMMARY AND CONCLUSIONS

Intraspinal therapy is to be condemned and the intravenous route advised if an antiserum is used.

Fifty-four patients with a fatality rate of 9.2 per cent were treated exclusively with antitoxin intravenously.

Spinal puncture may be necessary only for diagnosis. Frequent lumbar punctures for drainage are not to be advocated.

Approximately forty patients were treated without any intrathecal punctures.

The success of sulfanilamide therapy is to be attributed in part to the fact that ordinarily no intraspinal treatment is administered.

Permanent benefit for the relief of intracranial pressure by means of spinal fluid withdrawal is questionable.

Antitoxin or serum and sulfanilamide combined is recommended for superior treatment. Good results may be obtained with either one alone without intraspinal therapy.

Advantages which may be expected from the treatment of meningitis without intraspinal therapy are lower fatality rates, more prompt recoveries, few, if any, lumbar punctures required, minimized complications, opisthotonos rare, blockage problems unusual, intracranial pressure signs not observed as frequently as when numerous punctures are made for withdrawal of spinal fluid, discomfort and pain diminished, secondary infections as a result of many spinal taps eliminated, chance of injury to intervertebral disks reduced, hospitalization time shortened and recurrence of infection seldom observed.

THE TEN COMMANDMENTS FOR THE TREATMENT OF COMPOUND FRACTURES

JAMES E. M. THOMSON, M.D.

LINCOLN, NEB.

Increasing interest in this important subject is evidenced by the recent frequent contributions to medical literature. What was learned from the last World War, plus the increasing number of casualties from modern transportation, farm and industrial accidents, has made possible a clear conception of what is demanded in the way of treatment for compound fractures. The fact that perhaps more than 95 per cent of compound fractures are given first aid by laymen and surgical attention by general practitioners rather than by orthopedic and fracture surgeons presents an important challenge to these specialists to maintain constant refreshing interest essential to insure the general application of the basic principles of treatment, not only among physicians but among first aiders as well. Too often first aid and initial medical treatment is inadequate and responsible for unnecessary secondary trauma to an extremity. In other words, it is the man who attends the case in the first six to ten hours who determines the success or the failure of treatment. The specialist gets the wreckage for salvage.

The difficulty in standardizing methods is the fact that each compound fracture offers a different problem from every other compound fracture, sufficient to tax the judgment of the best trained surgeons. No single program or procedure is adaptable in all cases. Elbert H. Caldwell¹ aptly comments "The result of any procedure depends as much on the surgeon and his application as on the merits of the procedure." There are, however, virtues in almost every procedure that might be applicable under certain circumstances. Therefore, to treat compound fractures one must be broad minded and honest but critical in one's judgment and evaluation of procedures and apply them as the need arises.

The objects of treatment should be² (1) to care for the general condition of the patient, (2) to obtain healing of the broken bone with the best possible alinement of fragments and the least possible impairment of function and (3) to prevent or control infection. Therefore any recommended procedure of treatment for such serious and potentially serious injuries as compound fractures should comprehend every phase that would in any way favorably influence the outcome of the case.

Purely for the sake of impressing myself with the importance of a routine procedure to follow in the treatment of compound fractures, I have called my rules "the Ten Commandments for the treatment of compound fractures." Not like the original commandments, however, which have stood the test of time, these commandments have been changed with our changing ideas and methods; but in the main they have served as a constant reminder against omission and commission. Every commandment will not apply to every compound fracture, but good judgment and experience will check out the unessential.

Read before the Section on Orthopedic Surgery at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

1. Caldwell, E. H.: The Treatment of Compound Fractures, *Arch. Surg.* 35: 368 (Aug.) 1937; *Am. J. Surg.* 43: 554 (Feb.) 1939.

2. Darrach, William: Compound Fractures, *Arch. Surg.* 40: 821 (May) 1940.

FIRST COMMANDMENT.—*Splint and immobilize a compound fracture at the scene of the accident and transport the patient with celerity and great care to a hospital adequately equipped for treatment.*

It is deplorable that the first step is usually carried out by laymen who are inexperienced and overzealous well wishers and that the average ambulance called is unequipped or the physician who is summoned is untrained to meet this situation. The work of the various organized fracture committees has scarcely scratched the surface in stimulating in the minds of the populace the importance of this vital commandment in regard to first aid care and the relation that it bears to the ultimate end result. Much more can be done in the way of education along this line.

Although the patient may not exhibit apparent evidence of shock as he lies by the ruins of an overturned car, this is a potential complication of every severe compound fracture. Therefore it is important to keep him warm and protect him from the elements while waiting for an ambulance or physician. The protection of secondary trauma during transportation is best prevented by adequate 'splinting where he lies,' with Thomas (for lower extremity injuries) and Murray-Jones (for upper extremity injuries) splints in the approved manner. If these are not available, wooden splints, taking in the joints above and below the site of fracture, are acceptable. Gentle handling is most important. If the compounding is from within, outward traction is less desirable, as there is always the possibility of carrying contamination into the depths of the wound. However, with early débridement it is not of vital importance that a first aider diagnose and distinguish whether the compounding is from within or from without. The important thing, after all, is the immediate immobilization with moderate traction and the rapid transportation to a hospital where adequate care can be given. The most that should be done to the wound is the application of a sterile dressing, if available. A tourniquet or hypnotic may be necessary as an immediate first aid measure.

SECOND COMMANDMENT.—*Make an emergency case out of every compound fracture, giving the earliest possible adequate treatment.*

Admission to the hospital should imply emergency attention in the operating room and an x-ray examination with a portable machine. Minutes and hours must be economized for success. Prompt cooperative efforts among the surgical, resident, operating room and x-ray staffs are absolutely essential. I believe that the only exception to this routine is when the severity of the injury is such that shock is, in the experienced judgment of the surgeon, such a complicating factor as to warrant delay for resuscitative measures. It often pays to wait long enough to give 1,000 or 500 cc. of 5 or 10 per cent dextrose solution, or even a transfusion, than to subject a shocked patient to a long anesthetic and a surgical procedure. Usually an hour or two at the most after arrival at the hospital is sufficient for such resuscitation. In cases of severe compound fractures of the bones of children and of elderly persons, the potential factor of shock makes delay for restorative measures of major importance. Those in the extreme age groups are more susceptible to shock than the adult in the in between group and should be given the greatest consideration.

However, the chances of eliminating infection are reduced with each hour of delay. From six to ten hours after the accident, infection has gained a foot-

hold in the tissues and is hard to combat. Examination, palpation and manipulation, which lend themselves to unnecessary roughness and possible secondary trauma, are to be avoided. Inspection and x-ray examination should prove sufficient to justify sound judgment and decision with respect to a suitable *modus operandi*. When the splints are removed the position and traction should be maintained on a fracture table or other traction apparatus. A general anesthetic is usually preferable.

THIRD COMMANDMENT.—*Scrub the limb about and away from the wound with green soap and flowing sterile water for ten minutes.*

After the patient has been anesthetized, the splint removed and traction established by manual holding or by a traction device on a fracture table, a dry shave should start preparation of the extremity. With sterile hands and scrub brush the surgeon continues the preparation of the extremity by scrubbing with green soap and a stream of flowing warm sterile water from an elevated jar through a sterile tube. The water should drain away from the wound, which should be protected by frequent changes of dry sterile gauze dressing. (Ether or benzine may be used to remove grease from the skin.) Next the wound itself is superficially irrigated with warm water or physiologic solution of sodium chloride and the foreign material and clots allowed to be washed out. A sterile gauze dressing is placed on the wound and the cutaneous surface is painted with a mild antiseptic (merthiolate, metapen or weak tincture of iodine). The area is now draped in the conventional manner.

FOURTH COMMANDMENT.—*Debride every wound thoroughly with proper respect for anatomic structures and close those wounds which experienced surgical judgment seems to justify.*

No matter how small the wound, and whether from within or from without, conservative, intelligent débridement carries a tremendous influence in obtaining a clean wound. A puncture wound may carry clothing, leather or dirt into the bony fragments. Even though the wound is separated from the fracture by muscle or fascia, if infected material is carried in, the fragments may ultimately be involved. The added trauma of débridement and cleanup to the skin and superficial soft tissues of the underlying area will in no wise influence primary healing. An understanding of what constitutes a thorough débridement is essential. The operator, with a sharp scalpel, should start at a point farthest away from the dependent portion of the wound and remove not only the cutaneous edge but also attached injured and devitalized tissue. Next, clots and foreign material are picked out; devitalized, lacerated muscle tissue and shreds are removed by sharp dissection. A constant stream of warm sterile physiologic solution of sodium chloride aids in cleaning out the debris and in pointing out, by freshening the structures, further injured tissue shreds to be removed; bleeding points can be spotted and injured nerves and tendons identified. As the bleeding points are spotted they should be tied off but should not be roughly grasped by forceps with a mass of muscle, as this will strangulate the area clamped and leave a fertile medium for bacterial propagation. Severed nerves and tendons should be repaired, and even major blood vessels when possible. One might add another commandment: "After débridement, do not swab or pour into a wound any strong astringent antiseptic, as it coagulates and further devitalizes fresh tissue, thereby making a clean wound virtually a classic

medium for bacterial invasion." I would not consider such a procedure appropriate in performing a tendon transplant or herniotomy. If one is not satisfied with the thoroughness of the débridement and salt solution cleansing, no damage seems to be done by irrigating the wound with an aqueous solution of merthiolate; however, vigorous swabbing should be avoided, as it stimulates bleeding, which should have been arrested.

Small wounds, which comprise most compound fractures, are usually of the "from within out" type and can be closed after conservative débridement; but rare surgical judgment and long experience are needed to know which of the severe wounds can be safely closed with a reasonable expectation of not having infection develop. However, I close loosely almost every wound if it can be done without putting the tissues under too much tension. In two instances plastic shifting of flaps has proved successful with superficial lateral slits to insure against stretching; but such ventures are seldom indicated and should be performed with grave apprehension as to their outcome.

FIFTH COMMANDMENT.—*Reduce, after débridement, every compound fracture and firmly fix the fragments in place.*

Here, I believe, lies the secret of more often obtaining union, even in spite of infection, and also of obtaining a better functional result. It has long been a recognized fact that improper alinement and apposition, and inadequate fixation of bone fragments, form a most reasonable cause for delayed or nonunion with or without infection. This fact is just as true in simple fractures as in compound fractures. It is particularly essential that an adequate reduction be obtained, since compound fractures already communicate with the outside world. Immobilization may be accomplished by means of wires or pins above and below the fracture which, when embedded in casts or splints, frequently stabilize the reduction and prevent loss of position. Often accurate impingement of the reduced fragments furnishes sufficient internal fixation. However, none of these methods give the rigid fixation essential to promote early healing of the fractured fragments of long bones. Slight movements may injure the granulations and osteogenic reconstructive processes and may thereby open new fields for bacterial invasion. Metal plates, screws, wires and nails have been used in the field of compound wounds and also, when possible, have been inserted through incisions away from the compound wound. More recently stainless steel plates have been successfully used. Certain of these metals do not corrode, nor are they affected by body fluids (Sherman,³ Darrach²). When the plates used are of the same stainless metal as the screws there is no electrolytic or tissue reaction; they hold tight and do not seem to influence infection when present. When they have served their purpose they can be removed. Our experience with metal fixation of compound fractures has been limited to vitallium plates and screws, which I believe, as does Willis C. Campbell,⁴ furnish a perfectly adequate means of rigid fixation; their use is warranted more often than it is employed. The reports of Venable and Stuck⁵ with regard to the inertness of vitallium in the tissues have been substantiated in my modest clinical experience not only in simple fractures

but in compound fractures as well. I now use it nearly always in every case of compound fracture in which rigid fixation is necessary in maintaining reduction, particularly when there is considerable comminution. However, one who attempts such measures in surgery must be master of the most meticulous surgical technic. Not only must he stock the various sizes and types of plates and screws and have the proper tools with which to handle the fragments, plates, screws, nails, wires and pins but above all things he must have profound experience and knowledge of how to use them. These procedures should be done with the minimum amount of trauma to the fragments and soft tissues and should never be attempted by the occasional operator on fractures. Unless a man is constantly doing this kind of work he has absolutely no business fooling with internal fixation.

SIXTH COMMANDMENT.—*Coat the wound with crystals of sulfanilamide and give sulfanilamide or its derivatives orally as indicated.*

The use of sulfanilamide in compound wounds was called to my attention early in 1938 by J. Albert Key⁶ in referring to the then unpublished work of Jensen, Johnsrud and Nelson.⁷ I have followed similar measures in every compound fracture since and feel that, although sulfanilamide may slow primary wound healing slightly, it has a markedly deterring effect on local infection. I always accompany this by the oral administration of sulfanilamide or, when this is not tolerated, deep muscular injection is used in adequately prescribed therapeutic doses. Occasionally I use it orally and hypodermically, as does Campbell,⁴ in the preoperative and postoperative care of certain extensive reconstructive operative procedures in which there is a potential possibility of lighting up latent infection, with equally gratifying results. Crystals are also used as a thick dusting powder over small punctured wounds after débridement or over sutured closure of compound fractures. I realize that the fifth and sixth commandments offer exceedingly controversial ideas and recognize the fact that sufficient experimental work has probably not been done to justify such empiric use of this drug as a prophylactic measure, but my clinical experience has seemed to warrant its continued use in surgery in the manner described. Should one's judgment with regard to primary closure be wrong and infection develop in the wound, it can be recognized early by the physical and clinical symptoms and inspection of the wound through the fenestrated cast. The stitches should be removed and the wound opened wide and packed with sterile petrolatum gauze (Orr treatment⁸). After long experience with this method since its inception I am convinced that as a dressing in a deep wound which is already infected there is no irrigation used in any other treatment that compares with it. Wounds that are left open owing to extensive loss of tissue or potential infection are coated with sulfanilamide crystals and gently packed with petrolatum gauze. Dressings are changed only when a malodorous condition exists or excessive drainage

endangers the immobilized fractures in the cast. With this, of course, oral administration of sulfanilamide is essential.

SEVENTH COMMANDMENT.—*Immobilize compound fractures in a plaster of paris cast, adequately fenestrated for the observation of the wound and surrounding tissues.*

The more rigid the immobilization the better are the chances of avoiding infection and promoting healing not only of the bones but of the soft parts. It is my belief that, although metal splints and mechanical apparatus are extensively used in the larger clinics, where there are many assistants, assistant assistants, fellows, residents, interns and splint orderlies to look after them, they are responsible for many of the subsequent infections, delayed unions and nonunions, because of the fact that they are so often getting out of adjustment and balance, thereby constantly causing movement and irritation to the injured structures. On the other hand, for the surgeon in private practice, without the numberless attendants and assistants that a large clinic offers, a well padded, properly applied plaster cast which immobilizes the joints above and below the site of the fracture is not only the best

TABLE 1.—*Forty-Nine Patients Having Compound Fractures*

method of immobilization but allows him hours of peaceful rest and satisfaction that he could never obtain if he were harassed by the worries of how the traction and countertraction were holding in every case of compound fracture. The cast should be well padded with felt over the bony prominences, and the entire extremity with sheet-wadding bandage. It should be strong enough to allow generous fenestration over the site of the wound and fracture for constant observation and dressing. If there is any evidence whatever of swelling, the entire length should be split, not only the cast but the padding as well, and the edges spread. However, under ordinary circumstances, when the limb is properly swung up under a Balkan frame and not allowed to assume a position of dependence, one seldom sees sufficient swelling to warrant splitting. However, those without sufficient experience in applying well fitting casts had better be safe than sorry by following the rule of splitting every cast. Constant observation is the rule. Pain, swelling or impairment of circulation, one or all, are symptoms that signify trouble that must be corrected. The rules I follow for the types of casts are: For compound fractures of the hand and forearm the cast should extend from the axilla to the base of the fingers, and farther if indicated, with the elbow flexed at an angle of 90 degrees in supination or pronation, depending on the type of fracture. Fractures of the humerus are placed in an arm and body spica in an

appropriate position of rotation and abduction. Compound fractures below the knee are treated in a cast which extends from the groin to the toes, with the knee appropriately flexed and the foot at a right angle with the leg. All other compound fractures of the lower extremities are treated in a single or double spica cast in appropriate abduction and flexion.

EIGHTH COMMANDMENT.—*Give in every case of compound fracture at once a prophylactic injection of antitetanus serum combined with the Bacillus welchii-perfringens serum.*

In a few compound fractures that occur it may not be necessary to take this precaution, but why should one take the chance when there is absolutely no way of being sure that tetanus or gas gangrene may not develop? One minim (0.06 cc.) or so of the serum intradermally a half hour prior to the full injection has prevented any serious serum reaction. With observation of the eighth and ninth commandments I have not (I knock on wood as I write this) had a single case of tetanus or gas gangrene in over five years.

NINTH COMMANDMENT.—*Give a prophylactic dose of x-rays twice daily for three or four days over every compound fracture.*

James F. Kelly⁹ has successfully treated many cases of gas gangrene with x-rays and has recommended as a prophylactic dose from 30 to 50 roentgens twice a day for three or four days. I have followed this practice in nearly every case for the past few years, and

as a result I know little regarding this complication except what appears in the literature.^{9a}

TENTH COMMANDMENT.—*Use pectin therapy in all superficial open wounds.*

As petrolatum gauze forms the best dressing for deep wounds, so a 2 per cent aqueous solution of pectin saturated gauze forms, in my experience, the best dressing for superficial wounds. From a scientific standpoint this substance is of unproved value in the treatment of wounds. There has been no sound foundation for the assumption that pectin solution has any bactericidal properties in the wound. I do know that under certain circumstances¹⁰ streptococcus and other pathogenic bacteria do not live in this medium. However, when used as a dressing, 2 per cent aqueous nickel pectin has a profound absorptive and hygroscopic influence which actually licks up superficial pus, secretions and debris and seems to stimulate clean, fresh granulations and peripheral scarring, offering a delightful surface for skin grafting and secondary closure. Further, it is comfortable to the patient. I have also found pectin particularly useful in preparing old burn granulations for skin grafting.

CONCLUSION

Just as the Lord's Ten Commandments are never always obeyed, so it is with these ten commandments for the treatment of compound fractures. I have not always followed these principles completely. There are times when they will not all apply. They simply furnish a standard set of rules to follow for guidance. My idea has been that by using them I seldom overlook a single factor which might contribute to the better functional end result. I realize that I do some things that are not generally approved or well founded. However, I am convinced that they apparently do no harm but seem to contribute to fewer complications and better end results. I feel sure that if every surgeon treating fractures would set up a complete procedure covering every phase or possibility connected with the treatment of compound fractures and have his staff follow it implicitly for five years he would find that his results for that period would be far superior to any similar previous period. The statistical information with respect to a study of my last forty-nine patients who have had compound fractures is given in the tables.

1307 N Street.

9a. AUTHOR'S NOTE. My attention has been called to the danger of combining x-ray and chemotherapy in the treatment of gas gangrene. It is apparent that a choice must be made of one or the other in each case. However, we have noted no ill effect from their use as prophylactic measures where smaller doses of x-rays and sulfanilamide are used.

ABSTRACT OF DISCUSSION

DR. ROBERT W. JOHNSON JR., Baltimore: Dr. Thomson has covered almost all the sins of omission and commission that the surgeon can fall into in dealing with compound fractures. I have found that students are leary of a decalogue or other Biblical reference and I have condensed my admonitions to them in an alliterative manner into five principles: splinting, shock, surgery, sulfanilamide and serum. They seem to remember that, and I was pleased in looking over the examination papers a few weeks ago to find that I did not have to fail any one on the question of how to deal with a compound fracture of the femur from the moment of onset to six months after it had occurred. I want to point up Dr. Thomson's admonition in the first commandment to avoid undue speed in the transport of the patient to the hospital. Prompt action is necessary but bumpy handling is bad. In the third commandment I particularly liked his emphasis on the use of plenty of running water as a cleansing agent and also in the use of that same agent mechanically irrigating the wound during the surgical process of débridement, and also his insistence on the avoidance of astringent antiseptics in and around the wound. I find some reason to add caution to his suggestion that fixation plates be used in all compound fractures. He does qualify it, but a great many fractures are treated in hospitals where it is difficult to get adequate assistance and where adequate supplies are not available, so I think that his caution with regard to that should be emphasized because plating a fracture without adequate assistance is no easy job and certainly prolongs shock and trauma if it is not done properly. With regard to sulfanilamide, I am for it from the ground up, but I have used it only by mouth rather than in the wound itself. We have in sulfanilamide a unique agent which acts through the blood stream as a deterrent of infection; the use of it in the wound perhaps should be further checked, despite the enthusiastic reports that have come from a number of sources. I should like to add a point which is important: Fractures, in small communities especially, should all be in the hands of a single surgeon rather than in the hands of men who deal occasionally with fractures. In that way the individual who handles fractures gets plenty of practice, and as Dr. Hammond of Easton, Md., pointed out in a paper read before this section two years ago, it accomplishes astounding results. I have been following his work for years and I want to say that that is one point wherein the medical profession by unselfish cooperation can accomplish a lot for its patients.

DR. DONALD E. MCKENNA, Brooklyn: Dr. Thomson has created a group of surgical commandments which are highly commendable. If each hospital or staff would arrive at such a formula as his institution has, it would be a great advantage in the management of compound fractures. Plenty of our large city hospitals do not see too many compound fractures. I had a hasty survey made yesterday of the Methodist Hospital fracture service. Of 1,264 fractures, there were only fifty-four compound fractures in the last two years and some odd months, or 4.2 per cent, whereas from a definite knowledge of a small suburban hospital within 100 miles of New York, I know that the incidence is over 10 per cent. Except in large industrial centers and in places among our urban population where compound fractures are liable to occur, on the waterfront, and elsewhere, even general hospitals do not see too many of these lesions. The compound fractures are emergency procedures. It is an error to temporize. The small puncture wound should be enlarged. To deny its potential wickedness is to abrogate the virtues of proper transportation, prophylactic tetanus and perfringens therapy, and efficient control of shock and proper immobilization. There is a school of thought which teaches that irrigation is to be avoided. I am in accord with the author who advocated mechanical flushing, not with a medicine dropper or bulb syringe but, to quote Dr. Thomson, "with a stream of flowing warm sterile water from an elevated jar, through a sterile tube." I would add the precaution about leaving bone fragments which are in any sense attached to viable tissue in situ. In débridement one is apt to sacrifice some of these fragments. When a compound lesion is close to a joint, I prefer skeletal traction rather than internal fixation, but when otherwise I am in accord with

The results of these investigations showed that destruction of the adrenal cortex was followed by a marked excretion of sodium and chloride in the urine, a pronounced drop in the blood concentration of these ions, an increase in the blood potassium, and hemoconcentration and nitrogen retention. Treatment was directed toward reestablishment of a normal blood electrolyte pattern. This was accomplished both with the aid of injections of cortical extract and with the addition of large quantities of salt (from 10 to 20 Gm.) to the diet. Wilder and his co-workers³ pointed out the importance and need for the restriction of the potassium intake in the diet.

Although this represented an improvement in the treatment of Addison's disease, it still left much to be desired. The adrenal cortex extract was available in limited quantities and was of limited potency. The large quantities of salt which patients had to consume were irksome to them, and the improvement in the general condition of these patients was not unduly striking. It was evident that further advancement in the treatment of this disease was dependent on the preparation of a more potent extract which could preferably be prepared synthetically.

In 1936 and 1937 Mason, Myers and Kendall⁴ and de Fremery and his co-workers⁵ isolated corticosterone and dehydrocorticosterone in crystalline form from the extracts of the adrenal cortex and found that they could maintain adrenalectomized animals in good condition. A short while later, Steiger and Reichstein⁶ announced the preparation of desoxycorticosterone acetate from stigmasterol, and subsequently Reichstein and von Euw⁷ succeeded in recovering this compound from an extract of the adrenal cortex. Levy-Simpson⁸ used desoxycorticosterone acetate in the treatment of two patients with Addison's disease and found that it exercised an effect qualitatively similar to that of adrenal cortex extract.

In 1938 Thorn and his co-workers⁹ used desoxycorticosterone acetate in the treatment of bilaterally adrenalectomized dogs. They found that it was effective in maintaining these animals in good condition despite a diet low in sodium and chloride. Withdrawal of the drug resulted in a prompt diuresis with loss of sodium and chloride ions in the urine, a decrease in urinary potassium, hemoconcentration and elevation of blood nonprotein nitrogen, and the development of symptoms of adrenal insufficiency. Thorn, Howard and Emerson¹⁰ subsequently used this compound in the treatment of eight patients with Addison's disease. They found that treatment in doses of from 2 to 30 mg. daily resulted in a marked improvement in the clinical con-

dition of the patient, as well as the restoration of the blood electrolyte pattern to normal. These changes occurred without supplementary treatment with sodium salts or a decrease in the potassium content of the diet. The authors felt that results of treatment with desoxycorticosterone acetate resembled in every way the effect obtained with a potent cortical extract. Ferrebee, Ragan, Atchley and Loeb¹¹ treated thirteen patients with Addison's disease with intramuscular desoxycorticosterone acetate and propionate. They found that improvement was greater than from any previous therapy. Their results were in general agreement with those reported by Thorn and his group.¹⁰ In three of their patients, however, definite hypertension developed during the course of treatment, and ten of their patients had edema, which varied from mild puffiness of the face and ankles to massive anasarca. Of this group of ten, cardiac insufficiency developed in three.

In 1937 Deanesly and Parkes¹² reported that the subcutaneous implantation of pellets of estrogens and androgens produced a prolongation of the hormonal effect. Ingle and Mason¹³ succeeded in prolonging the survival period of adrenalectomized rats by implanting subcutaneously tablets composed of a mixture of cholesterol and compounds derived from the adrenal cortex. Thorn and his co-workers,¹⁴ utilizing the technic employed by Deanesly and Parkes, studied the effect of subcutaneously implanted pellets of desoxycorticosterone acetate in bilaterally adrenalectomized dogs and six patients with Addison's disease. They find that results obtained with the pellets are similar to those with intramuscular injections except that the former effect a greater economy in the use of the drug. They conclude that the life of a pellet depends on its consistency and weight. The quantity of desoxycorticosterone acetate liberated appears to vary with the surface area of the pellet. The pellets are absorbed at the rate of 0.25 to 0.40 mg. daily.

RESULTS

In the present paper we present the results obtained in five patients with Addison's disease, who were treated with intramuscular injections of desoxycorticosterone acetate in oil. Four of these patients subsequently received pellets of the synthetic crystalline compound implanted subcutaneously. One of the patients was a female and four were males. Their ages varied between 11 and 44 years. All the patients had been previously treated with large amounts of salt by mouth, and four of them at some time or other received injections of adrenal cortex extract:

CASE 1.—D. G., a woman aged 21, was admitted to the hospital March 21, 1938, because of marked asthenia, pigmentation, nausea and loss of 20 pounds (9 Kg.) in weight. The blood pressure could not be determined by auscultation, but by palpation the systolic pressure was found to be 70. The blood urea nitrogen was 17 mg. per hundred cubic centimeters,

Johns Hopkins Hosp.* **64**: 155 (March) 1939. Thorn, G. W.; Howard, R. P.; Emerson, Kendall, Jr., and Firor, W. M.: Treatment of Addison's Disease with Pellets of Crystalline Adrenal Cortical Hormone Implanted Subcutaneously, *ibid.* **64**: 339 (May) 1939.

blood chlorides 93 milliequivalents per liter, sodium 131.3 milliequivalents per liter and sugar 79 mg. per hundred cubic centimeters. She was treated with a constant intravenous drip of isotonic saline solution and during the ensuing twenty-four hours received approximately 3,000 cc. As a result of the intravenous therapy she improved sufficiently to continue oral treatment with salt. During the course of the next week she was given 9 Gm. of sodium chloride and 4 Gm. of sodium bicarbonate daily by mouth. Her blood pressure rose to 95 systolic, 60 diastolic; the weight was 113 pounds (51 Kg.). The blood chemistry values had now altered, so that the sodium was 138.3, chlorides 100.0 and potassium 6.3 milliequivalents per liter. The blood sugar rose to 100 mg. per hundred cubic centimeters; the urea nitrogen, however, remained stationary at 16 mg. From June 16 to 19, approximately three months, after oral treatment with salt had been started, the patient without our knowledge omitted her daily supplementary

Chart 1.—Course in case 1.

salt feedings and was promptly precipitated into addisonian crisis. The blood pressure fell to 75 systolic, 58 diastolic. The blood values were sodium 122.3, chlorides 93.5 and potassium 7.2 milliequivalents per liter. The urea nitrogen was 34 and sugar 90 mg. per hundred cubic centimeters. The carbon dioxide content was 22.6 millimols per liter. The volume of packed red cells was 54 per cent, and the body weight had fallen to 104 pounds (47 Kg.).

During the three months period in which the patient was treated with salt alone, we find that the blood electrolytes were maintained at a fairly normal level. However, at no time did she feel well. She continued to complain of profound asthenia and anorexia and could spend but little time out of bed. June 19, when the symptoms of crisis developed, intramuscular injections of desoxycorticosterone acetate were started. She received 20 mg. of the synthetic substance daily for two days, then 10 mg. daily for four days. In addition, during this six day period she received 16 Gm. of salt by mouth daily. At the end of this period her weight had risen to 116 pounds (53 Kg.), the blood pressure was 90 systolic, 65 diastolic and the hematocrit reading had fallen to 35 per cent. The blood values now were sodium 139.9, chlorides 113.5 and potassium

5.1 milliequivalents per liter; the urea nitrogen was 12 mg. per hundred cubic centimeters and the carbon dioxide content was 23.0 millimols per liter. From June 24 until July 15 the patient received 10 Gm. of supplementary salt by mouth and 5 mg. of desoxycorticosterone acetate intramuscularly daily, but from July until the end of the first week in September the daily supplementary salt intake was reduced to 5 Gm. At the end of this period the patient's clinical condition improved remarkably. She was up and out of bed, she had a sense of well-being, her appetite had improved, and the pigmentation had decreased somewhat. The blood pressure was now 150 systolic, 94 diastolic; the weight was 117 pounds (53 Kg.). The blood electrolyte studies showed the sodium to be 137.8 milliequivalents per liter, urea nitrogen 10 mg. and sugar 90 mg. per hundred cubic centimeters, carbon dioxide 24.8 millimols per liter, and the blood hematocrit value 43 per cent. Because of the hypertension, the supplementary salt feedings were entirely discontinued, and the desoxycorticosterone acetate was reduced to 2.5 mg., given intramuscularly daily. After one week of this regimen the blood pressure fell to 112 systolic, 78 diastolic; the blood sodium was 127, chlorides 102 and potassium 9.2 milliequivalents per liter. It was obvious that 2.5 mg. of the drug given intramuscularly daily without additional salt was inadequate to maintain a normal electrolyte pattern. Despite the abnormalities of the blood constituents, however, her sense of well-being continued, and the patient was up and about without any discomfort.

September 16 ten pellets of crystalline desoxycorticosterone acetate were implanted subcutaneously, the average weight of each pellet being 128 mg. It was calculated that approximately 0.3 mg. of the compound would be absorbed daily per pellet, the total daily amount being 3 mg. This is equivalent in therapeutic effect to about 5 mg. given intramuscularly. She received no supplementary salt by mouth. One week after the implantation of the pellets her weight was 120 pounds (54 Kg.), the blood pressure was 138 systolic, 92 diastolic, and the hematocrit level had fallen to 34 per cent. The blood values now were sodium 141.8, chlorides 107.5 and potassium 3.6 milliequivalents per liter. She felt perfectly well and was discharged from the hospital. November 10, two months after implantation of the pellets, the blood pressure had risen to 150 systolic, 95 diastolic, and on slight exertion it would rise to 180 systolic, 110 diastolic, which was associated with dyspnea and cardiac palpitation. Her weight was 122 pounds (55 Kg.), and the blood electrolytes were entirely normal.

During the period of treatment with desoxycorticosterone acetate there occurred a tremendous improvement as far as the symptoms related to the Addison's disease were concerned, despite the fact that no additional salt was required. However, the symptoms of mild cardiac failure were a cause for considerable concern; they were probably due to the liberation of excessive amounts of the desoxycorticosterone acetate. She is to be readmitted to the hospital for the removal of some of the implanted pellets.

CASE 2.—S. R., a man aged 19, was admitted to the hospital Nov. 25, 1938, with all the characteristic signs and symptoms of Addison's disease. On admission, the hemoglobin was 101 per cent and the red blood cell count was 7,500,000, showing considerable hemoconcentration. The blood sodium was 128.3, chlorides 85 and potassium 8.1 milliequivalents per liter. The blood urea nitrogen was 27 mg. and the sugar 100 mg. per hundred cubic centimeters. His weight was 113 pounds (51 Kg.) and blood pressure 90 systolic, 50 diastolic. The patient was given 12 Gm. of sodium chloride and 4 Gm. of sodium bicarbonate daily by mouth. In addition, during the first two weeks he received 2 cc. of adrenal cortex extract subcutaneously daily. After seven weeks of treatment with salt alone he was discharged from the hospital considerably improved, although he continued to complain of weakness and some anorexia. His blood pressure on discharge had risen to 112 systolic, 70 diastolic, and the blood sodium had increased to 135 milliequivalents per liter.

He was readmitted to the hospital May 19, 1939. During the intervening six months period he had been taking daily 12 Gm. of salt and 4 Gm. of sodium bicarbonate. His weight had increased to 133 pounds (60 Kg.), and the blood pressure was 110 systolic, 80 diastolic. The blood chemical values now were sodium 133.1, chlorides 100 and potassium 9.6 milliequivalents per liter, urea nitrogen 15 and sugar 90 mg. per hundred cubic centimeters, and carbon dioxide content 25.5 millimols per liter. During this period of supplementary salt treatment he continued to feel weak, had one or two daily episodes of nausea and was entirely incapable of doing any work.

One week after his readmission to the hospital, treatment was begun with desoxycorticosterone acetate. He received a daily intramuscular injection of 5 mg. of the drug in oil, and the supplementary sodium chloride intake was reduced to 10 Gm. After one week of this treatment, the blood electrolytes returned to normal levels, the sodium increasing to 137.8 and chlorides to 105 milliequivalents per liter. His weight increased to 138 pounds (63 Kg.), but the blood pressure stayed relatively stationary at 105 systolic, 65 diastolic. Despite the improvement in blood chemistry values there occurred no change in symptoms. He continued to complain of weakness and occasional episodes of nausea. Three weeks after the intramuscular injections were started, ten pellets of crystalline desoxycorticosterone acetate were implanted subcutaneously in the right infrascapular region. The average weight of each pellet was 103 mg. For two days after the implantation of the pellets he continued to receive the supplementary 10 Gm. of salt by mouth. At the end of this period he began to complain of headache, vomiting, edema of the face and hands, palpitation and exertional dyspnea. It was noted that a gallop rhythm had developed. His weight at this time was 138 pounds and the blood pressure had risen to between 130 systolic, 85 diastolic, and 136 systolic, 102 diastolic. The blood electrolytes, however, showed no material change from the previous levels. The sodium was 137.7, chlorides 108.5, and potassium 7.1 milliequivalents per liter. The urea nitrogen was 10 and the sugar 80 mg. per hundred cubic centimeters, while the carbon dioxide content was 23.9 millimols per liter. The daily salt intake was promptly reduced and the headache, vomiting, and edema disappeared. On discharge from the hospital July 18, 1939, one month after implantation of the pellets, he was taking only 2 Gm. of additional salt by mouth, his weight was 139 pounds (63 Kg.) and the blood pressure 124 systolic, 80 diastolic. The blood electrolytes were entirely normal. Symptomatically there occurred a marked improvement. He felt quite strong and was anxious to return to work. Anorexia and nausea had entirely disappeared. He has been followed regularly with repeated blood chemistry determinations. In October 1939 the additional salt by mouth was entirely discontinued. In December 1939, six months after implantation of the pellets, the patient continues to feel extraordinarily well. His blood pressure, however, has risen to 140 systolic, 90 diastolic. The blood electrolyte pattern continues to remain normal.

This patient, like the one previously described, could get along only poorly when treated with large amounts of salt alone. Even after administration of a potent adrenal cortex extract there was but little change in the clinical condition, although the blood chemical constituents were approximately normal. Following the administration of the desoxycorticosterone acetate, however, there occurred marked improvement in symptoms, the most striking of which was the tremendous increase in the sense of well-being. There were improvement in strength and appetite and a complete disappearance of the gastrointestinal symptoms. However, on implantation of pellets there developed hypertension and edema and some signs of heart failure, although relatively mild in degree.

CASE 3.—J. S., a man aged 44, was admitted to the hospital May 24, 1939, because of pigmentation, progressive asthenia and fatigue, anorexia, nausea, and loss of 16 pounds (7 Kg.)

in weight in two weeks. His blood pressure on admission was 100 systolic, 75 diastolic and he weighed 118 pounds (53.5 Kg.). He presented a characteristic picture of Addison's disease in mild crisis. The blood chemical values were sodium 127.6 and chlorides 94.0 milliequivalents per liter, urea nitrogen 19 mg. and sugar 105 mg. per hundred cubic centimeters. Treatment was begun with 15 Gm. of salt by mouth daily in addition to the salt content of the usual ward diet. At the end of one month of this regimen, his weight was still 118 pounds and the blood pressure 105 systolic, 65 diastolic. The blood sodium rose only slightly to 130.5 and chlorides to 97 milliequivalents per liter while the potassium was 7.4 milliequivalents. The blood urea nitrogen was 14 mg., and the volume of packed red blood cells was 41.5 per cent. There was no improvement in the clinical condition. He continued to complain of profound weakness, anorexia and nausea. June 29, in addition to treatment with 15 Gm. of salt, intramuscular injection of 5 mg. of desoxycorticosterone acetate daily were started. After eleven days of the combined therapy his weight increased to 125 pounds (57 Kg.), the blood pressure rose to 125 systolic, 80 diastolic,

Chart 2.—Course in case 2.

and the hematocrit value dropped to 28 per cent. The blood electrolytes now were perfectly normal. The blood sodium was 138.3, chlorides 105.5 and potassium 4.5 milliequivalents per liter, while the urea nitrogen was 13 and the sugar 90 mg. per hundred cubic centimeters. The carbon dioxide content of the blood was 29 millimols per liter. Although there occurred this marked improvement in the laboratory observations, clinical improvement was not so striking. The anorexia and nausea had subsided considerably but the patient continued to complain of weakness. The supplementary sodium chloride intake was reduced to 10 Gm. daily, and seventeen days later thirteen pellets of the crystalline desoxycorticosterone acetate were implanted subcutaneously in the left infrascapular region. The average weight of each pellet was 126 mg. It was calculated that the daily absorption of the drug from the pellets would total 3.9 mg. Six weeks after implantation of the pellets the symptoms of Addison's disease had improved considerably. Anorexia and nausea had vanished, and the patient felt considerably stronger. However, he now began to complain of precordial pain on exertion, dyspnea and cardiac palpitation. The precordial pain was somewhat relieved by glyceryl trinitrate. The blood pressure at this time was 140 systolic, 85 diastolic, the hematocrit value was 33.5 per cent and blood

sodium 139, chlorides 105 and potassium 5.9 milliequivalents per liter. The supplementary salt by mouth was entirely discontinued but the precordial discomfort continued and the patient was now seriously handicapped by his cardiac symptoms. Two months after implantation of the pellets the blood electrolytes continued to be normal but the blood pressure varied from 150 systolic, 80 diastolic to 184 systolic, 98 diastolic. It was decided to remove some of the implanted pellets, and September 26 four pellets were removed surgically.

The blood pressure promptly fell to 140 systolic, 85 diastolic and the attacks of palpitation and precordial pain were somewhat less frequent. At present, one month after removal of the four pellets, the blood pressure continues at 145 systolic, 88 diastolic, his weight is 121 pounds (55 Kg.) and the blood sodium is 137.5, chlorides 102.5 and potassium 3.6 milliequivalents per liter. The blood urea nitrogen is 7.0 and the sugar is 80 mg. per hundred cubic centimeters. The patient has had no additional salt during this period. However, the anginal symptoms persist, although with somewhat lessened intensity.

Chart 3.—Course in case 3.

We feel that it will be necessary to remove more pellets, despite the fact that the amount of the drug being absorbed is only approximately 2.7 mg. daily.

This patient represents the third of this series, all of whom have behaved in essentially the same fashion. After treatment with desoxycorticosterone acetate they progressed remarkably well from the point of view of Addison's disease. This subjective and objective improvement continued without the necessity for taking additional salt by mouth. However, in all three patients hypertension has developed, and in two of them it was severe enough to warrant removal of some of the implanted pellets.

CASE 4.—L. C., a man aged 34, was admitted to the hospital Nov. 20, 1939, after being treated elsewhere for Addison's disease. For a month prior to admission to the hospital he had received 16 Gm. of salt by mouth daily, plus injections of 5 cc. of adrenal cortex extract twice a week. On admission to the hospital his weight was 129 pounds (58.5 Kg.), blood pressure 94 systolic, 66 diastolic and hematocrit value 47 per cent. The blood sodium was 127 and chlorides 100 milli-

equivalents per liter. The blood urea nitrogen was 21 and sugar 95 mg. per hundred cubic centimeters. The carbon dioxide content was 26.5 millimols per liter. From November 20 until November 30 he was treated with 15 Gm. of salt by mouth without any additional extract. At the end of this period of time, he had lost 2 pounds (0.9 Kg.) in weight but there was no change in the blood electrolytes, blood pressure or hematocrit reading. He continued to complain of nausea and profound asthenia, and the intensity of pigmentation increased. November 30, daily intramuscular injections of 5 mg. of desoxycorticosterone were started in addition to the 15 Gm. of salt. There occurred an immediate improvement in clinical symptoms and by December 11 he felt well enough to get out of bed; nausea and anorexia had entirely disappeared and he felt considerably stronger. His weight at this time had increased to 132½ pounds (60 Kg.), blood pressure was 102 systolic, 68 diastolic and the hematocrit level had fallen to 39 per cent. The blood electrolyte pattern returned to normal, the blood sodium being 140.6 and chlorides 107 milliequivalents per liter; blood urea nitrogen was 6 mg. and sugar 60 mg. per hundred cubic centimeters, while the carbon dioxide content was 28.1 millimols per liter. December 19 the injected dose of desoxycorticosterone acetate was reduced to 2.5 mg. daily while the supplementary salt feeding had been decreased to 5.0 Gm. daily. Eight days later with this regimen his weight had increased to 136½ pounds (62 Kg.); the blood pressure and hematocrit level remained constant at 106 systolic, 64 diastolic and 38 per cent respectively. The blood sodium was 143.9 and chlorides 109 milliequivalents per liter, urea nitrogen 12 mg. and sugar 75 mg. per hundred cubic centimeters, and the carbon dioxide content was 25.8 millimols per liter. The desoxycorticosterone acetate was now reduced to 1.5 mg. with 5 Gm. of salt daily. Six days later there was no change in the weight or blood pressure, and the blood chemical constituents remained perfectly normal. Clinically the patient felt very well. Jan. 6, 1940, three pellets of crystalline desoxycorticosterone acetate were implanted subcutaneously in the left infrascapular region. The average weight of each pellet was 110 mg. and it was calculated that he would absorb approximately 0.9 mg. of the drug daily. In addition he receives 5 Gm. of salt by mouth. At present, two weeks after the implantation of the pellets, he continues to feel perfectly well and is anxious to go back to work. There has been no further change in his blood pressure, and the blood electrolytes remain normal.

In this case we attempted to avoid the development of the complications in other cases following the use of the synthetic compound. In previous cases the therapeutic goal desired was the ultimate treatment with desoxycorticosterone acetate without the supplementary daily salt feedings. This required the use of rather large amounts of desoxycorticosterone, and consequently there developed hypertension, edema or both. In this last case the amount of the substance decided on was less than the amount that would be required if no additional salt was to be used. To date this patient has had none of the sequelae seen in our patients treated with the large doses of desoxycorticosterone acetate. With the aid of a small amount of salt (5 Gm.) daily in addition to his regular diet he is doing extremely well.

CASE 5.—This case will be reported in greater detail elsewhere by the department of pediatrics of the hospital. Briefly, S. S., a boy aged 11, was admitted to the hospital April 15, 1938, in severe addisonian crisis, with a well defined history of Addison's disease of at least six months' duration. On admission his weight was 72 pounds (33 Kg.), blood pressure 64 systolic, 42 diastolic, blood urea nitrogen 51 mg. per hundred cubic centimeters, and blood sodium 114.7 and chlorides 85 milliequivalents per liter. He was given large quantities of intravenous saline solution and dextrose, and April 25 the blood pressure was still 66 systolic, 42 diastolic, blood urea nitrogen 26 mg. and sugar 100 mg. The blood electrolytes were sodium 120.5, chlorides 85 and potassium 6.9 milliequivalents per liter.

Clinically he was somewhat improved, although he continued to be listless and rather drowsy.

He was started on 10 Gm. of salt and 5 Gm. of sodium bicarbonate daily by mouth. Under this regimen he became more alert and seemed somewhat stronger. June 10, six weeks after oral salt therapy was begun, he was still seriously ill.

TABLE 1.—*Dextrose Tolerance Curves* in Patients with Addison's Disease Before and After Treatment with Desoxycorticosterone Acetate Blood Sugar, Mg./100 Cc.*

Patient and Type of Therapy	Control	$\frac{1}{2}$ Hour	1 Hour	2 Hours	3 Hours
1. D. K.					
Treatment with salt alone	55	85	125	110	95
Treatment with desoxycorticosterone acetate, 5 mg. intramuscularly for 68 days	75	125	105	90	85
2 months after pellets were implanted	70	135	115	120	120
2. S. R.					
Treatment with salt alone	85	90	85	85	70
Treatment with desoxycorticosterone acetate for 4 months (injections and pellets)	60	85	75	60	40
4. L. C.					
Treatment with salt alone	50	130	80	85	90
Treatment with desoxycorticosterone acetate for 3 weeks (injections)	90	105	100	85	80
5. S. S.					
Treatment with salt alone	60	115	80	90	90
Treatment with desoxycorticosterone acetate for 2 months (injections)	80	105	80	95	75

* 1.75 Gm. of dextrose per kilogram of body weight was administered to the fasting patient.

The blood urea nitrogen was 26 mg. and sugar 50 mg. per hundred cubic centimeters, while the blood sodium was 125.2 and chlorides 105 milliequivalents per liter, although the blood pressure had gone up to 96 systolic, 56 diastolic. At this point he began to receive 2 cc. of adrenal cortex extract subcutaneously in addition to the salt. Four months later (October 6) his weight had increased to 79 pounds (36 Kg.), the blood pressure was 100 systolic, 60 diastolic and the blood electrolytes were entirely normal. He was discharged from the hospital and during the course of the next year he received 15 Gm. of salt by mouth and 2 cc. of adrenal cortex extract subcutaneously twice a week. One year after discharge from the hospital, Oct. 4, 1939, he had gained 18 pounds (8 Kg.) in weight and felt fairly well; his blood pressure was 100 systolic, 70 diastolic, blood urea nitrogen 19 mg. and sugar 90 mg. per hundred cubic centimeters. The blood sodium was 139, chlorides 106.5 and potassium 3.6 milliequivalents per liter. The hematocrit value was 40 per cent. He was taken off salt and extract for about forty-eight hours; at the end of this period he began to complain of weakness, nausea and abdominal cramps. There was no change in blood pressure, but the hematocrit value increased to 43 per cent. The blood urea nitrogen had risen to 24 mg. The blood sodium had fallen to 135 and the chlorides to 101.5 milliequivalents per liter, while the potassium increased to 5.4 milliequivalents. October 10 treatment was begun with desoxycorticosterone acetate; during the course of the next month the daily dose was reduced to 1.5 mg., while he received 5 Gm. of additional salt by mouth. The patient felt well, the blood pressure was 104 systolic, 70 diastolic and the weight 99 pounds (45 Kg.), and the blood electrolytes were entirely normal. At this point it was decided to discontinue the desoxycorticosterone acetate entirely but to increase the daily supplementary salt intake again to 15 Gm. Two weeks later, although the blood chemistry values were still perfectly normal, he began to complain of some weakness and his appetite was reduced. His sense of well-being was not as marked as during the period of treatment with the desoxycorticosterone acetate.

COMMENT

The treatment of Addison's disease with desoxycorticosterone acetate represents a marked advance in therapy. It produces not only dramatic changes in the blood chemistry but equally striking changes in the well-being of the patient. The effect of the synthetic compound on the blood electrolytes is qualitatively the same as that with adrenal cortex extract except that the effect of the synthetic substance is more pronounced. With adequate doses of the desoxycorticosterone acetate there occur a retention of blood sodium and chloride and a potassium diuresis. With the reestablishment of a normal blood electrolyte pattern, evidences of dehydration and hemoconcentration disappear and the urea nitrogen returns to normal. In contrast to the effect of the synthetic drug on the blood electrolytes, no effect is produced on carbohydrate metabolism. In four cases (table 1) dextrose tolerance tests were done before and after treatment. There was no demonstrable change in carbohydrate metabolism as a result of the treatment. The tests were performed from three weeks to four months after therapy with the synthetic compound was started.

The effect of the desoxycorticosterone acetate on the blood pressure is apparently dependent on dosage. When the amount of the drug used is in excess of the daily requirement of the patient there will occur an increase in blood pressure which may even reach alarming levels. Thus three of our patients developed a definite hypertension, and one of this group manifested anginal symptoms which incapacitated him almost as completely as did the original uncontrolled Addison's disease. When the dosage is reduced the blood pressure will fall. Although the effect of the synthetic material on the blood pressure occurs promptly, hypertensive levels are not reached until after two to four weeks of constant therapy. It might be proper to point out here that treatment with the old adrenal cortex extract produced no marked changes in the blood pressure.

TABLE 2.—*Amount of Desoxycorticosterone Acetate Absorbed Daily from the Implanted Pellets as Determined by Removal of Pellets from Two to Six Months After Implantation*

Patient	Date of Implantation of Pellets	Weight of Pellets, Mg.	Date of Pellet Removal	Weight of Individual Pellets Removed, Mg.	Desoxy- corti- costerone Absorbed Daily, Mg.
1. D. G.	9/16/39	125	12/11/39	96.7	0.30
3. J. S.	7/27/39	126	9/25/39	110.9 110.9 114.9 110.0	0.28 0.28 0.20 0.20
			1/24/40	65.1 74.8 78.6 85.0	0.22 0.23 0.27 0.22

The effect of the synthetic drug on the pigmentation of Addison's disease is relatively slight and probably nonspecific in character. Following adequate treatment and after the general condition of the patient improved considerably there occurred some decrease in the intensity of the pigmentation. In no instance did the pigmentation entirely disappear. Whatever effect is exercised is probably the result of increased hydration of the patient.

The effect of the pellets is identical with that of the injection of the synthetic substance in oil. It must be

remembered, however, that when pellets are used the daily requirement of the desoxycorticosterone acetate is approximately from 60 to 75 per cent of that which is needed when the drug is given by injection. The pellets, then, have the advantage of being the more economical. However, after the pellets are implanted, control of the patient is difficult and the development of complications due to excessive medication requires surgical intervention to reduce the dosage. In deciding on the number of the pellets to be implanted in a patient with Addison's disease, the daily requirement must first be determined with intramuscular injections of the synthetic compound. Calculations are based on the fact that a pellet weighing from 100 to 150 mg. will liberate approximately 0.3 mg. of the drug daily (table 2). We feel that it is wiser to implant less than the required number of pellets and to supplement treatment with some additional salt by mouth (from 3 to 5 Gm.) daily. In this way the dangers of unfortunate complications are lessened. The dangers to be borne in mind in the use of this new drug are development of hypertension, edema and heart failure. The intelligent use of the synthetic compound requires careful clinical observation of the patient and adequate laboratory facilities for repeated blood electrolyte determinations. A word of caution must be said about indiscriminate use of this synthetic drug in various forms of asthenia. It is a powerful weapon, and until its pharmacologic actions are better understood its use should be restricted to patients with well defined Addison's disease.

SUMMARY

1. Five patients with Addison's disease were treated with intramuscular injections of desoxycorticosterone acetate in oil.

2. In four of these patients pellets of crystalline desoxycorticosterone acetate were subsequently implanted.

3. The disturbed blood electrolyte pattern is readily restored to normal with the aid of this new drug. It also exercises a marked salutary effect on the sense of well-being of the patients.

4. It produces marked increase in the blood pressure but exercises no effect on carbohydrate metabolism and on the pigmentation.

5. Pellets are more economical to use than are injections. They are, however, associated with greater danger of complications, since the control of the amount of the drug liberated is difficult and may require surgical intervention.

6. The dangers to be borne in mind with the use of the synthetic compound are development of hypertension, edema and heart failure.

7. Pellets weighing approximately 125 mg. liberate from 0.20 to 0.36 mg. of desoxycorticosterone acetate daily.

1155 Park Avenue.

Tuberculosis Death Rate.—In most parts of the world where statistics have been kept, the death rate from tuberculosis has been steadily declining for about one hundred years. About 1780 the estimated death rate from consumption in England was 650 per 100,000 living inhabitants. It is expected that the death rate in the United States will fall below 45 per 100,000 in 1940. According to Dublin, this will represent a decline of 37 per cent in the last ten years, and a decline of 61 per cent in the last twenty years. In forty years the death rate has dropped 76 per cent.—Webb, Gerald B.: Tuberculosis—Present and Future, *J. Lab. & Clin. Med.* 26:287 (Nov.) 1940.

ROENTGENOLOGIC GROUP EXAMINATIONS FOR PULMONARY TUBERCULOSIS

IN NEGROES IN CHICAGO: PRELIMINARY REPORT

ROBERT G. BLOCH, M.D.
WILLIAM B. TUCKER, M.D.
AND
J. EDMOND BRYANT, M.D.
CHICAGO

Because of the high incidence of tuberculosis among persons who have been exposed to massive infection from others, x-ray examinations of such contacts have been a routine practice in the Chest Clinic of the University of Chicago since 1929. The convincing experience that early tuberculosis is most successfully found among those who, because of the absence of symptoms, are unsuspected led in 1932 to the initiation of a case finding program among students, faculty and hospital employees. The results were in keeping with those

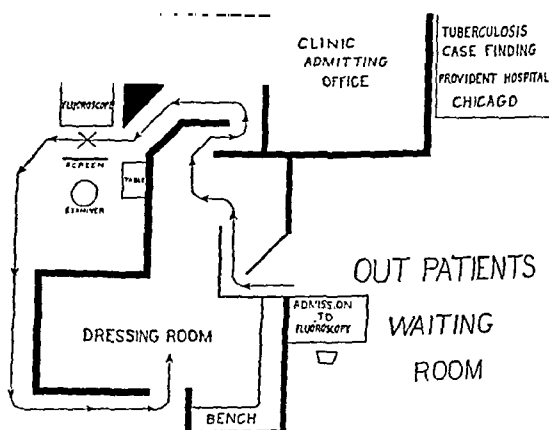

Fig. 1.—Arrows indicate route of patient through fluoroscopic plant.

reported from similar institutions and gratifying enough to continue the examinations as a university and hospital routine.

In 1934 the practice was extended to the expectant mothers seen in the clinic of the Chicago Lying-in Hospital because of the many unpleasant experiences with previously unrecognized tuberculosis among that group of patients and because they are an easily accessible group of healthy although physiologically strained persons. To date about 10,000 pregnant women have been examined. The published results from the first 4,000 indicated that slightly more clinically important tuberculosis is found by routine fluoroscopy of the chest than syphilis is by routine serologic tests.

SELECTION OF GROUP

Since the studies among the previously mentioned groups would not indicate the real proportions of the problem of unsuspected tuberculosis in the general population, it was desirable to gain access to still another

This work was financed by a grant from the Julius Rosenwald Fund. From the Department of Medicine, University of Chicago, and the Provident Hospital.

Drs. R. W. Vines, J. L. Batty, H. H. McClanahan, and S. J. Gray of the Department of Medicine, University of Chicago, gave valuable assistance in the examinations.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

group which, judged by its average economic status and according to published reports, would give a more accurate picture of the universal distribution of the disease. Because of our failure to reach those persons employed in the industries, we were glad to accept the generosity of the Julius Rosenwald Fund and the invitation of the Provident Hospital of Chicago to examine the patients in the outpatient department of that institution. The higher mortality of tuberculosis in the Negro than in the white population—in Chicago seven times higher—makes this a particularly suitable group. Furthermore, no large scale case finding program among Negroes carried out by x-ray examination has been reported from a metropolitan area until an extensive report was published by Edwards¹ from New York. His figures on the incidence of tuberculosis are close to our own. Of the proposed 30,000 examinations, 10,000 have been completed. The analyzed results and experience from the first 9,000 are presented in this preliminary report.

Although clinic patients cannot be considered a group of supposedly healthy persons, the application of the principle to examine all of them, regardless of the nature of their complaints, seems to have resulted in a fair cross section of the Negro population. To improve further the representative nature of the group, Negroes of nonpatient status were then invited to be examined. Up to the present time these nonclinical persons constitute nearly one third of the total number examined and tend to equalize the results of this survey with those of a wholly nonclinical group.

Although the object of the program is essentially the search for tuberculosis in adults, we included any children presented to us by relatives or guardians and, in addition, several special groups of juveniles (Boy Scouts and high school students). The distribution of nonclinic persons and clinic patients and the differential between new and return patients among the latter classification are indicated in table 5.

To avoid delay in the routine function of the clinic and to plan the program along with the work of the clinic staff, the examinations were carried out next to the waiting room of the outpatient department and admitting office. They precede the examinations in the clinics. A special fluoroscopic plant (fig. 1) was constructed through which large numbers of persons can pass in a very short time. A standard vertical fluoroscope was reconstructed to permit unhindered passage behind the screen (fig. 2). The examination of approximately 16,000 new patients annually together with return patients and special groups requires considerable speed and a minimum of friction in the organization.

The recording system consists of a form containing four different parts representing the diagnosis (to be attached to the clinic record), the results of examinations (which are retained by the investigators), a requisition blank for x-ray films and a memorandum for the social worker (fig. 3). The presence or absence of pathologic changes is indicated by checking the printed items. Very little writing is required. The patient's personal record is filled in by helpers who are provided by the WPA and NYA organizations.

CHARACTERISTICS OF GROUP

The 9,000 persons examined included 1,000 juveniles, consisting of two special groups examined: 506 members of Negro Boy Scout troops and 494 students of

one of the large Negro high schools of Chicago's south side. The average age for the entire group was 35.5 years, with a standard deviation of 15.5 years, which means that two thirds of the group fall between 20 and 51 years of age. These distributions are illustrated in figure 4.

Approximately twice as many females as males were examined, the proportion being 63.5 per cent females and 36.5 per cent males.

Approximately half of the total number examined were return patients to the Provident Hospital Clinic. The remainder were fairly evenly divided between new clinic patients and nonclinic persons.

Fig. 2.—Vertical fluoroscope constructed for group examinations. Lateral arm has been replaced by overhead beam from which fluoroscopic screen is suspended, permitting continuous passage of patients behind screen from right to left. Shutter controls are attached to fluoroscopic screen by way of wire cables illustrated in the foreground.

Figure 5 shows the distribution for these three clinical classifications, for the entire group and without the 1,000 children.

OTHER OBSERVATIONS—NONPULMONARY DISEASE

In addition to finding disease in the lungs, it was inevitable that the fluoroscopic technic should reveal the presence of other, nonpulmonary, disease in the chest. In fact, 20 per cent of the total were found to have other disorders of the chest.

In most instances of the occurrence of nontuberculous disorders, x-ray examinations were not ordered. A complete analysis of the various nontuberculous conditions found has not yet been compiled. Very common were evidences of disease of the cardiovascular system, such as enlarged and mitral hearts, widened aortic shadows and aneurysms; evidence of old pleural involvement in the form of pleuritic residuals, some of them calcified. Scoliosis was not infrequent. One instance

1. Edwards, H. R.: Tuberculosis Case Finding: Studies in Mass Surveys. *Am. Rev. Tuberc. (supp.)* 41:3 (June) 1940.

of spontaneous pneumothorax (without symptoms) was discovered and a small number of cases of pneumonic infiltration, pulmonary tumor and other nontuberculous pulmonary diseases were found. Of the minor abnormalities of structure, various anomalies of the bony thoracic cage, including cervical ribs and vena azygos lobes, were the most common. Two cases of situs inversus were discovered. Among the 560 x-ray films taken, the most common nonpulmonary conditions were pleuritic residuals and cardiac enlargement.

ANALYSIS OF X-RAY FILMS

Among the 9,000 persons examined, in 574 instances (6.4 per cent) there were fluoroscopic changes sufficient to justify ordering x-ray examinations, one to every 15.7 persons examined. Of the 574 x-ray examinations ordered, 560 actually were done, or 97.6 per cent. Considering the difficulty of persuading persons to return a second time for the purpose of having the x-ray examination made, this figure is very high, and much

type of pathologic condition and as to the stage of the tuberculous disease.

Seventy-two per cent were minimal, 19 per cent moderately advanced and 9 per cent far advanced.

The productive-fibroid type of pathologic change was found to have the greatest incidence, occurring in 31.3 per cent of the cases. Second most frequent were the fibrocaceous and fibrocalciocaceous types, occurring in 22.5 per cent. The clinically important pathologic types, exudative caseous and exudative, occurred in 13.6 per cent and 9.9 per cent, respectively (table 2).

INCIDENCE OF DISEASE

To the 380 cases presenting positive signs on x-ray examination were added five cases in which the fluoroscopic observations were sufficiently definite to be unmistakable, making a total of 385 persons of the 9,000 examined, or 4.3 per cent, who were found to have definite pulmonary tuberculosis. Eighty-seven were judged to have clinically unimportant pulmonary disease

[illegible]

Fig. 3.—Type of record filled out for each patient examined by fluoroscopy. Sheets are numbered serially. Stub at left (A) is used only when important clinical disease is found, for purposes of clinical and social follow-up. Main portion of sheet (B), containing diagrammatic representation of pathologic condition, is attached to patient's clinic record. Upper right hand sheet (C) is retained in files permanently. It includes the final diagnosis made from x-ray films and the statistics for a study on tuberculous calcifications. Stub in lower right hand corner (D) is used only when x-ray examination is required and ordered on main portion of sheet (B) to confirm fluoroscopic examination.

of the success obtained in this regard was due to the unceasing efforts of the social service worker.

Of the fourteen persons who had manifestations on fluoroscopy not confirmed by x-ray examination (2.4 per cent of x-ray examinations ordered), five presented sufficiently definite conditions to be included with those judged to have tuberculosis. The other nine have been assumed to have no pulmonary disease or have clinically unimportant disease.

Of the 560 x-ray films taken, 32.2 per cent proved to show no pulmonary disease, 15.5 per cent to show definite but clinically unimportant pulmonary disease and 52.3 per cent showed definite pulmonary tuberculous pathologic changes judged to be of actual or potential clinical importance. Thus, in 380 instances x-ray films were positive, 77.1 per cent judged to be clinically important and 22.9 per cent clinically unimportant. These figures are summarized in table 1.

The 374 persons whose x-ray films were judged to show definite pulmonary changes were classified as to

(though in many instances such persons are under clinical observation and their contacts have been examined), an incidence of 1 per cent. Thus 298 persons, or 3.3 per cent of the entire group, proved to have clinically important pulmonary disease.

The incidence of tuberculosis was actually slightly greater than these figures indicate when the special groups of Boy Scouts and high school students were excluded, the respective figures for all pulmonary disease and clinically important tuberculosis then being 4.65 and 3.6 per cent (table 3).

INCIDENCE OF TUBERCULOSIS ACCORDING TO AGE

In conformity with the observations of many investigators, there was found to be a considerable difference in the incidence of tuberculosis in various age groups. In general, the incidence was above the average for the entire group below 10 years of age and above 45 and below the average for the group between the

ages of 10 and 45. Table 4 gives the figures for all positive pulmonary manifestations by age groups, for both the 1,000 children of the special groups and the 8,000 others examined.

When only clinically important tuberculosis of the lungs is considered, there is also a marked variation as to the incidence in different age groups. The greatest incidence is in the very young and the old. As compared with a total group average incidence of 3.3 per cent, children under 15 and men and women above 50 were found to have a relatively high incidence and those between 15 and 50 a relatively low incidence. This is illustrated graphically in figure 6 for the group exclusive of the 1,000 juveniles. It is to be observed from these figures that persons in the third decade of life had the lowest incidence of important pulmonary disease.

INFLUENCE OF VARIOUS FACTORS ON INCIDENCE OF DISEASE

When the total group of 9,000 is subdivided into several categories, according to various criteria, and the incidence of tuberculosis in each category is calculated, additional information is gained as to where tuberculosis may be found. Table 5 summarizes these figures. The 1,000 Boy Scouts and high school students have been excluded from this analysis, and only clinically important pulmonary disease is considered, but inclusion of the 1,000 juveniles and of clinically unimportant pulmonary disease does not greatly alter the results.

Sex.—The incidence of clinically important pulmonary disease is approximately twice as frequent in males as in females.

Clinical Status.—Patients coming to the clinic for the first time have nearly half again as much tuberculosis as do patients previously registered and examined.

Nonclinic persons examined were found to have an incidence of clinically important pulmonary disease slightly higher than return clinic patients but definitely lower than new clinic patients.

Calcifications.—Those patients found to have calcifications, either parenchymal or glandular, proved to have more clinically important pulmonary disease than persons without such calcifications. This difference was more marked when the 1,000 children of the special groups were included.

COMMENT

In previous communications we have expressed and reiterated our trust in the fluoroscopic method of examination if it can be supplemented by chest films for all positive and suspected conditions. No detailed discussions of the merits of fluoroscopy as compared to other methods of x-ray examination are offered in this paper. An appraisal of the value of the various techniques employed in group examinations of the chest, including the tuberculin test, has been attempted in another article.^{1a} Recent controversy, however, induces

us to add here that we consider fluoroscopy a wholly reliable method if it is employed by physicians who are well trained in pulmonary pathology and in the technic of the method. Its use is limited not by an inferiority to other means of examination in recognizing disease but rather by its inability to furnish an objective, per-

1a. Bloch, R. G.: Case Finding in Tuberculosis, to be published in the American Review of Tuberculosis, February 1941.

manent record of negative observations; this makes it impracticable wherever a liability for the examining agency may be involved as, for example, in the entrance examinations for the fighting forces. Employing fluoroscopy in the present survey but using single paper

Fig. 4.—Age distribution of 8,915 persons examined by fluoroscopy.

roentgenograms for reasons of economy, we found that the paper films were not nearly as satisfactory for qualitative analysis of tuberculous lesions as is possible from transparent films. In the clinical appraisal of our observations we have refrained from using the terms "active" and "inactive" and similar qualifying adjectives. While the activity of many tuberculous lesions from x-ray diagnosis alone cannot be doubted, there are many in which only clinical and sometimes prolonged observation can decide the degree of activity. Certainly the absence of activity cannot be determined except perhaps in small and definitely calcified foci. The terms "clinically important" or "clinically unimportant" under which the results have been grouped are not meant to express final judgment as to the clinical importance of the lesion but only to give our impression gained from the chest films. As a rule, we are not in a position to follow most of the patients clinically. The great majority are referred to the health authorities for further observation and care. As yet too little time has elapsed to appraise the correctness of our impressions. We are

Fig. 5.—Clinical status of 8,915 persons examined by fluoroscopy.

aware of the large number of small tuberculous infiltrations to which we attach clinical significance. We know that this may evoke some criticism and occasional ridicule. There seems to be widespread and considerable discrepancy between the desire to make a diagnosis of early tuberculosis and the attention which it receives after it has been found. The circumscribed "spot in the lung," often presented as negligible to the patient and

remaining untreated, is one of the most frequent small forms of caseous tuberculosis which may excavate rapidly. In figure 7 is demonstrated the excavation of two such lesions, discovered in supposedly healthy persons during group surveys.

Figure 8 demonstrates how a similar small focus developed into advanced tuberculosis during a period of seven years. These roentgenograms are of patients of the white race. There is reason to assume that the same lesions in a Negro would have developed more rapidly, other factors being equal.

The greater tendency toward exudative tuberculosis and unfavorable progression of tuberculous disease in the Negro compared with observations in the white race seems well established and is attributed to a lesser immunity of the race.² There is no discrepancy between this experience reported from autopsies and the clinical predominance of the productive types of disease found in surveys. The average age of our adult group was 37 years, whereas the largest number of deaths from tuberculosis in Negroes occurs during the third decade in life. It seems, therefore, that a large proportion of

Fig. 6.—Incidence of clinically important pulmonary disease found on fluoroscopy, by five year and ten year age groups (8,000 cases).

our patients are those who have been able to survive early exudative lesions by favorable tissue response in the lung. However, many of them remain, at best, stationary without signs of definite healing, which explains the much higher incidence of clinically important lesions (3.3 per cent) among the total of pathologic changes (4.3 per cent) than have been found in the white population, in which the respective figures are 1.2 per cent and 3.5 per cent.

The striking preponderance of minimal over moderately and far advanced tuberculosis in our group is almost the reverse of the distribution found in sanatoriums³ (fig. 9). While it demonstrates the essential

E.: The Frequency of Artificial Pneumothorax Refills in Tuberculosis: Preliminary Report, *ibid.* 35: 513-529 (April) 1937.

value of examinations among the unsuspected population, it may be due partly to the more frequent occurrence of productive lesions after the third decade of life and, to some extent, to our inability to bring under observation the patients with far advanced disease who

Fig. 7.—On the left, two patients with a subapical caseous minimal tuberculosis. On the right, the same lesions after excavation with resulting positive sputum and symptoms. The time interval during which excavation occurred in each case was about three months.

had been the source of infection of many of our patients with minimal infection. Insufficient funds did not permit the establishment of the extensive social service which would have been needed for that purpose. However,

Fig. 8.—Small tuberculous focus seen at left proved to be of great clinical importance by subsequent development into far advanced tuberculosis, as demonstrated at right.

these persons do not remain unnoticed but are brought to the attention of the city health authorities.

The higher incidence in juveniles, which is recorded in table 4 as above the average incidence of the total group, is not in accordance with the general experience

concerning the age distribution of tuberculosis. Our higher figures seem to be due to a practice of considering any not definitely calcified lesion in children as clinically important in order to insure continued clinical observation.

The occurrence and significance of calcification is an object of special investigation of our study. The detailed results will be reported elsewhere. For epidemiologic considerations it is interesting to note that the incidence of clinical tuberculosis in the presence of calcification was 1.6 per cent greater, or half again as high as in persons without calcified foci. This observation again throws doubt on the traditional conception of the protective value of first tuberculous infections.

That a special search for tuberculosis in a general clinic is not superfluous is demonstrated by the incidence of 2 per cent clinical pulmonary disease in the return patients of the clinic. It is a common experience

TABLE 5.—Influence of Various Factors on Incidence of Clinically Important Pulmonary Disease (7,915 Cases, Exclusive of Special Groups of Children)

Category	Total Examined		Incidence

that pulmonary lesions are overlooked in examinations in specialized clinic departments largely because of insufficient use of x-ray diagnosis. However, not only pulmonary disease is revealed by the addition of this routine to clinic work; the examiner at the fluoroscope is in a position to call the clinician's attention to large numbers of patients with extrapulmonary disease. This is indicated by the incidence of 20 per cent of such extrapulmonary pathologic changes among which cardiovascular disease is the most prevalent. To a large measure the figure is due to the frequency of vascular syphilitic involvement but more significantly also to the occurrence of enlarged and otherwise abnormal cardiac shadows seen in children whom we were able to refer to clinical examination. This experience alone seems to justify fluoroscopic group examinations among children.

Altogether, our experience so far has justified the time, effort and expense⁴ required by the experiment;

4. The cost of the survey, estimated on the basis of an expected number of 30,000 examinations, will be 10 cents per examination and approximately \$3 for the discovery of each clinically important case of tuberculosis. Since all physicians participating in the examinations are donating their services, the available funds were used for the establishment of the plant, for the purchase of equipment and for administrative expenses. Adequate remuneration of the medical examiners would about double the cost per case. This would still be lower than the expenditure for other tuberculosis surveys concerning which the information was available.

we wish to emphasize the necessity of roentgenologic group examination in the fight against tuberculosis in Negroes as well as in other groups of the population. A clinic offers the opportunity to conduct a routine roentgenologic search for unsuspected tuberculosis in a never ending flow of the populace without the necessity of solicitation. Since dozens of cases of tuberculosis are missed throughout the country every year in physicians' offices, in clinics and in hospitals, since thousands go through life unconscious of their disease and therefore do not seek medical help, in other words since tuberculosis is still one of the most urgent problems in the preservation of the health of the people and, furthermore, since all this is due to two factors, namely (1) that physical examinations frequently fail to reveal the disease and (2) that much active tuberculosis causes no symptoms, it is the demand of our time and of the better knowledge acquired in recent years that all physicians, wherever they practice their profession and whatever their special medical interest may be, help to educate the people that tuberculosis must be searched for everywhere and in everybody.

Fig. 9.—Comparison of stages of tuberculosis of groups under treatment in sanatoriums, reported to health authorities and found by fluoroscopy case finding program.

There is hope that group surveys on an ever increasing scale will be organized throughout the country and that we are not far from the day when laws and regulations will make an x-ray examination of the chest a prerequisite for employment in domestic service, in the teaching professions, in industry, in the fighting forces and for the issuance of a marriage license. It appears that there is a weapon available for the fight against tuberculosis which, without any spectacular advance in scientific research, can carry the profession far toward the elimination of the disease as a major public health menace.

The better opportunity of finding or, at least, of suspecting the presence of extrapulmonary disease adds to the value of such examinations in the admitting department of a general clinic. We suggest, therefore, that roentgenologic examination of the chest of all patients should become a routine procedure in all medical institutions.

950 East Fifty-Ninth Street.

ABSTRACT OF DISCUSSION

DR. MAX PINNER, New York: The authors have chosen the x-ray approach without previous tuberculin test. One should not draw general conclusions from this. Each worker should determine the feasibility or the advisability of doing tuberculin tests or not doing tuberculin tests before x-ray examination. In the population that Dr. Bloch and his collaborators have examined the incidence of negative reactors is undoubtedly minimal, and no saving would be had by doing tuberculin tests. On the other side, in rural communities it is probably advisable to do tuberculin testing first because from 50 to 70 per cent of x-ray films may be saved by this method. There is a great deal of discussion about the value and reliability of fluoroscopy as against roentgenography. I believe that it cannot be solved in a general way. Fluoroscopy presupposes, more than roentgenography, very careful training and experience, and whoever has it can probably go far with this method, complemented by x-ray films as indicated. In the surveys on Negroes, many were probably astonished that not a greater percentage was found; as a matter of fact, in surveys of Negroes and white people living under identical living conditions, such as done by Dr. Edwards in Harlem, the percentage of morbidity of Negroes was less than in white persons; nevertheless the mortality rate is a multiple of the white rate, indicating that the disease in Negroes is much shorter and much more rapid in development. This would indicate that an occasional survey in Negro groups is not of much use because not all the early cases which will develop next year are found in the surveys this year; it will be necessary to make the examinations at rather short intervals. The acuity of the disease in the Negro as compared with the white person I think is well exemplified by the autopsies such as my associates and I reported for Detroit and Chicago. One of the outstanding factors of differences statistically seen is the much greater frequency of disseminated lesions in the Negro as compared to the white person. Incidentally, in this autopsy work we were struck by the relative frequency of apparently completely healed, calcified, primary complexes in Negroes and particularly in Negroes who, on reinfection, developed lesions that looked very much like primary infections again. We concluded from that that the Negro who goes through his primary infection becomes allergic without increasing his immunity, as the white person apparently does.

DR. H. R. EDWARDS, New York: This paper in many instances is a close duplicate of the work we have been doing in New York. I should like to offer for comparison the results of 70,000 examinations in Harlem, by the rapid paper x-ray method, which I believe to be superior to fluoroscopy. The observations indicate in general about twice as much tuberculosis among the white population above 25 years of age as among the Negroes, whereas below that age the ratio is the reverse. In another study involving 53,000 recipients of home relief the same distribution by color and age was found. Our definition of clinically significant tuberculosis is essentially the same as that used by Dr. Bloch. The distribution by sex and color indicates white males 5.7 per cent, Negro males 3.4, white females 3.3, as compared with Negro females 2.2, an average of 3.1 considered active and 17 per cent considered arrested; also there is a higher percentage of arrested chronic pulmonary tuberculosis among white males and females than among Negro males and females. A chart representing some 169,000 individuals, ranging from high schools with four cases in a thousand to transient males with 43 cases per thousand convinces me that the problem of tuberculosis is closely allied to specific age, sex, racial and economic factors. It is primarily an adult problem, more serious among the Negroes and those living on low income or in tenement houses, and the unemployed than the employed and higher economic levels of society. About 70 per cent of the patients were found by the survey method in the minimal stage at a time before they have spread their infection to others and when the most can be done to restore them at the least cost to the community.

5. Tice, Frederick, and Hruby, A. J.: Collapse Therapy at the Chicago Municipal Tuberculosis Sanitarium: A Critical Study of 8,083 Cases, *Bull. City of Chicago Municipal Tuberc. Sanitar.* 15-16-17: 30, 1935-1936-1937.

DR. ARTHUR B. ROBINS, New York: I want to amplify some of the remarks made by Dr. Edwards in emphasizing the age factor in connection with the difference between white and Negro tuberculosis. I have been interested in the question of the relationship between mortality and morbidity. When I started this work I was struck by the fact that the group with the predominant mortality seemed to have the lower morbidity, and in every study that my associates and I have done that has been a consistent finding. Even in those under 25, among whom the morbidity in the Negro is higher in a ratio of about 4 to 1, the ratio of deaths is from 8 to 12 to 1; and, in those over 25 among whom the mortality is from four to five times as high, the morbidity is lower than in the white population. We have also been interested in the results of annual re-x-ray examinations of the patients and we have a group of about 9,000 individuals who were given x-ray examinations in the relief study in Harlem one year, and the negative ones given re-x-ray examinations the following year. In that group, which is made up of about 7,500 Negroes and 750 white persons, twenty-six cases of tuberculosis developed in people whose previous x-ray examinations had been entirely negative. It is of interest that twenty-one of those cases developed in the Negro group, two in the white group and three among Puerto Ricans. The incidence rates in those groups are approximately the same, although the group of 750 white individuals is too small to draw conclusions from. However, in an average period of eight months from the time of diagnosis, seven of the twenty-one cases developing in the Negroes have already proved fatal, indicating an annual mortality rate of 50 per cent in Negroes with negative x-ray examinations at the beginning of the study, who later developed tuberculosis. I think that this may have a great deal to do with the difference in morbidity and mortality figures, and I think it is rather an effective disposal of the objection that a major portion of those differences is related to the unwillingness of Negro patients to come in for x-ray examination or to accept treatment. We had no difficulty in getting those people, although they were classified as apparently healthy, back on two separate occasions, an average of a year apart.

DR. HAVEN EMERSON, New York: If Dr. A. J. Chesley of Minnesota is not in the room to give the information himself, I should like to call attention to a method of tuberculosis case finding that was applied, as far as I know, the first time in the laboratory of the Minnesota State Department of Health in the process of typing pneumonia sputum. All such pneumonia specimens were put through a routine examination for the tubercle bacillus, and 9 per cent were positive for the tubercle bacillus; of the cases of tuberculous infection so discovered, only 10 per cent had been previously reported as cases of tuberculosis to the state department of health. It is inexpensive, costing about 15 cents to have each pneumonia sputum examined for tubercle bacilli, and we are, as sanitarians, more concerned with the discovery of a case of tuberculosis with positive sputum in which recovery recently occurred from an acute pulmonary disease than with a large number of persons with relatively unimportant lesions, even though clinically significant, with negative sputum.

DR. ROBERT G. BLOCH, Chicago: Dr. Tucker has many more statistics on our observations which we could not show. There was also no time to go into the controversy as to the value of tuberculin case finding programs with x-ray examination alone. We have stated that we doubt the case finding value of tuberculin in the adult. All the x-ray methods have their advantages and disadvantages. We are aware that fluoroscopy has the disadvantage of not providing a permanent record and, furthermore, that it requires special training which not even the average chest specialist has. There needs to be a thorough training in the technic of fluoroscopy as well as in the pathology of the lung, and we ourselves have witnessed programs going on in which, on account of the inexperience of the examiners, the results were not as good as they might have been, and many cases of tuberculosis were missed. A word about the

examinations among students and nurses: One of the objects in presenting this paper was to point out that the medical public and the public at large have been induced to believe in recent years, by a flood of publications from medical schools, universities and hospitals, that tuberculosis is largely a problem of the college student, the medical student and the nurses. This is definitely not so. The incidence of tuberculosis among students and among nurses is not appreciably higher than that in the average population of the same age. Besides, these are very small groups and they are economically and socially good groups. It is needless to say that everything possible should be done to protect students and nurses against the hazards of infection. Beyond that nothing needs to be said about them in public health efforts to find tuberculosis in the general population. The groups in which tuberculosis needs to be looked for primarily are the groups that Dr. Edwards has just presented. With reference to Dr. Haven Emerson's remarks, I should like to say that the sputum examinations among pneumonia patients in Minnesota merely indicate that a lot of tuberculosis is still being misdiagnosed as pneumonia.

Clinical Notes, Suggestions and New Instruments

THE DIAGNOSIS OF HERNIA

STEPHEN A. ZIEMAN, M.D., CHICAGO

In a few weeks the selective service act will be in effect. Inauguration of a selective service brings a new responsibility to the medical profession. The decision as to the ability of any registrant to perform full military service depends on the professional judgment of the local examining physician. Rejec-

Fig. 1.—Usual method of hernial examination as described in textbooks.

tion of the candidate because of physical defect may prove demoralizing to the individual; mistake in diagnosis, costly to the government.

The presence of a hernia in men of the draft age is a deterrent to military service, while the widespread prevalence of hernia in men of this age group necessitates a correct understanding on the part of the physician as to what constitutes a hernia. I consequently propose the following considerations in the hope

that they may be helpful in the diagnosis and differential diagnosis of hernia. Mistake in this matter is less the fault of the examining physician than it is inaccurate surgical teaching on this subject. To instruct the student that an impulse

Fig. 2.—Author's method of examining for hernia, using right hand for right side of patient.

perceptible on coughing or straining while the examining finger is in the external inguinal ring is diagnostic of a hernia is to create a misconception. A little thought on this point will

Fig. 3.—Author's method of examining for hernia, using left hand for left side of patient.

demonstrate the fallacy. The insertion of a finger into the external inguinal ring (fig. 1) produces a cremasteric reflex and consequently the cord structures are retracted or pushed upward by such a procedure, not infrequently without pain. When the patient is now advised to cough, the contraction of this muscle is overcome and a sudden relaxation results in

the production of a thud on the examining finger from the cord structures.

Second, there are cystic and solid tumors, especially lipomatous masses in this region, which undergo a similar contraction owing to the action of the cremasteric muscle, and on its release these tissues may give an impulse and a false impression of a hernia.

Third, the differential diagnosis of hernia is not always an easy matter. Some surgeons challenge its possibility in many instances. To distinguish between a direct, an indirect or a femoral hernia with any degree of accuracy may constitute a surgical problem.

To help correct these conditions, I suggest a method which has proved very encouraging in clarifying these difficulties. The method (fig. 2), in brief, consists in placing the first, second and third fingers over the inguinal region in such a manner that the index finger rests on the so-called weak spot. The middle finger lies along the direction of the inguinal canal with the tip of the finger at the external inguinal ring, while the third finger controls the femoral canal and the fossa ovalis. With the hand in this position it is possible to perceive a peculiar sliding, pushing motion of a viscus under one or

Fig. 4.—Relationship of the various hernias to the examining fingers.

another of the examining fingers when the patient is directed to cough or strain. Thus immediately a direct, an indirect or a femoral hernia is determined. If there is a bulging mass apparent to the eye, the examining hand forces the mass inward and again coughing or straining immediately differentiates the type of hernia present.

The patient is always examined in the upright position with the examiner standing somewhat behind and to the right (figs. 2 and 3), using the right hand for a right inguinal hernia, and to the left, using the left hand for a left inguinal hernia. This method in no way distorts the relationships of the parts in this region and obviates a palpation artefact. A peculiar gurgling, sliding or slipping motion under one or another finger (fig. 4) alone determines the presence of a hernia. The feeling of solid or cystic masses results in an entirely different sensation. I moreover feel that straining is a better method for eliciting the essential diagnostic factor than is coughing.

The diagnosis of a hernia in many cases may be reached on careless inspection, but the method here proposed is particularly helpful in borderline cases, cases of relaxed abdominal muscles or large external inguinal rings. The method, furthermore, has been attested at the operating table, where patients have been operated on and no hernial sac was demonstrable.

The evaluation of any surgical procedure in the treatment of a systemic disease can be reached only after an adequate period of carefully controlled and unbiased trial. This trial demands that certain fundamental conditions be strictly adhered to: 1. The surgical procedure must be utilized in a large number of cases and must remain identical in all cases. 2. The selection of cases must be based on constant criteria, fully investigated in each case before operation. 3. Postoperative results must be judged by the same criteria in an identical manner and on as many occasions as possible. 4. All cases in which operation is performed must be included in the results. 5. The trial must extend over a sufficiently long period of time to eliminate mere temporary effect of the operative procedure.

It is our purpose in this paper to present evidence that the surgical treatment of hypertension has fulfilled the demands of such a trial and consequently should now take its deserved place in the armamentarium of treatment of this disease.

The history of the development of the surgical treatment of hypertension has been reviewed elsewhere.¹ At present four distinct operative procedures are most commonly employed. Their results, studied over a long period of time, must decide the relative merit of each. They are adrenal denervation by celiac ganglionectomy;² subdiaphragmatic, extraperitoneal, bilateral resection of the splanchnic nerves with removal of the upper two lumbar sympathetic ganglions and the intervening chain;³ bilateral transdiaphragmatic removal of the lower dorsal and upper lumbar sympathetic chain with its ganglions and the rami forming the splanchnic nerves,⁴ and bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy.⁵

The last named procedure was first introduced into this country by Peet in 1933 and has been used unaltered by him and his associates at the University of

Michigan Hospital since that time. More than 500 patients have been operated on by the Department of Neurosurgery by means of this technic. The results of the total series are comparable with those presented in this study.

It is not within the scope of this paper to review the experimental work on the etiology of hypertension⁶ nor will an attempt be made to define or classify the disease. Suffice it to say that evidence points to renal ischemia, no matter what the cause, as the usual basic factor in hypertension. The rationale on which we base our operative procedure is therefore the relief of renal ischemia by interruption of the sympathetic vasoconstrictor outflow to the kidneys.

The technic of bilateral supradiaphragmatic splanchnicectomy and dorsal sympathetic ganglionectomy has been described in detail.⁵ Briefly it consists of bilateral paravertebral incisions, usually under avertin with amylene hydrate anesthesia, centering over the eleventh intercostal space. A 4 cm. section of the eleventh rib is removed subperiosteally from a point slightly distal to its articulation with the transverse process of the vertebra. The parietal pleura is retracted, exposing first

the lower dorsal sympathetic chain with its rami forming the lesser splanchnic nerves, and still deeper the greater splanchnic nerve. A 9 to 13 cm. segment of the latter nerve is resected to its point of entry into the crus of the diaphragm. The sympathetic chain including the tenth, eleventh and twelfth ganglions and the lesser and least splanchnic nerves is next removed, the fibers of the diaphragm being split if necessary. The procedure is performed bilaterally in one stage. The average operative time is about one hour. The postoperative stay in the hospital averages about two weeks.

The selection of cases for operation for hypertension at the University Hospital is based on several relatively simple requirements. The patient is preferably not over 50 years of age, but numerous exceptions have been made. The renal function must be adequate as indicated by a urea clearance of more than 40 per cent of normal and a urine concentration above 1.012. No patient with a blood nonprotein nitrogen of more than 45 mg. per hundred cubic centimeters is accepted. The heart must be compensated and the general physical status of the patient adequate to withstand a major operative procedure. Patients with systolic blood pressures under 200 mm. of mercury are usually not advised to have the operation unless they have had an adequate

with a strong hereditary background and the typical hyperlabile type of pressure such a recommendation might be made. No patient is operated on whose hypertension is known to be the result of primary disease of the kidney or other organs. Thus an attempt is made to rule out the following preoperatively: glomerulonephritis, pyelonephritis, pyonephrosis, renal or adrenal tumor, or endocrine disturbances accompanied by hypertension. In other words, patients selected for operation are those suffering from a primary type of high blood pressure for which no organic cause can be found.

Herewith are presented the preoperative and postoperative results in 350 consecutive cases of hypertension in which bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy has been performed by one surgeon (Peet) since 1933. The methods of study and the criteria by which the results have been judged are also presented.

METHODS OF STUDY

Each patient is examined preoperatively in the departments of medicine, ophthalmology, cardiology and roentgenology. Kidney function studies include determination of urea clearance, urine concentration and blood non-protein nitrogen. Pyelograms are now made in all cases presenting the possibility of primary renal disease. A teleroentgenogram checked by an orthodiagram and an electrocardiogram are obtained in each case. Frequent blood pressure determinations are taken by several independent observers and the readings averaged.

Postoperatively the patient is advised to return at definite intervals for check-up examination. Because of financial reasons it has frequently been necessary to have the patient return for such studies at our expense. Funds for this purpose were available through special grants to the department of neurosurgery by Mr. Jeremiah Milbank and the Aaron Mendelson Memorial Trust Fund. Approximately 65 per cent of the 350 patients included in this study have returned for one or more examinations at postoperative periods of from nine months to seven years. Acceptable data in the remaining cases have been obtained through the cooperation of the home physician. In only four of the 350 cases

have we been unable to obtain reliable blood pressure determinations nine months or more postoperatively.

On his return for reexamination the patient was subjected to the following routine: Complete and detailed preoperative histories were personally retaken in order to check all preoperative data as to duration of hypertension, symptomatology and incapacitation. Interval histories were recorded in detail. The patient was reexamined by all departments which had examined him preoperatively, and these departments rendered an opinion as to the comparative progress or regression of the case in respect to their specific specialty. All postoperative statistics have been compiled on these opinions.

The blood pressure was taken at least once with the patient in a sitting position, four determinations being obtained from each arm. Whenever possible this was repeated subsequently. An arithmetical average of the systolic and diastolic readings was taken as the significant figure for that visit. It should be noted that these pressure readings were taken while the patient was ambulatory and under the considerable strain of frequent examinations by various departments as compared to preoperatively, when the pressure readings were usually taken with the patient on a regimen of bed rest.

Following this routine it was possible to obtain on each patient unbiased data and evaluation of the patient's course with regard to blood pressure, symptomatology, incapacitation, condition of the ocular fundus, renal function and cardiac status.

As a result of this comprehensive study, which has extended over a period of nearly seven years, an enormous mass of preoperative and postoperative data has been accumulated. Obviously such a fund of information could not be treated by ordinary methods. As a result, each specific item has been coded on tabulating cards, and the statistical correlations, appearing in the accompanying tables, compiled mechanically.⁷

CRITERIA

In order to evaluate the results of operation in the treatment of hypertension it was found necessary to

establish certain criteria by which all cases could be judged and from which statistics could be compiled. Obviously these criteria are, to a certain extent, empirical in character and are therefore open to criticism. In order to obviate as much of this criticism as possible, the specialists in each department were asked to estab-

lish their own criteria of normality and significant change. These criteria are as follows:

Significant reduction in blood pressure is considered as a drop of 40 mm. systolic and 15 mm. diastolic or more from the preoperative level. The blood pressure

Total cases.....	215	

value given for each postoperative check-up is the arithmetical average of all readings by the departments of medicine and neurosurgery. No pressure is considered significantly reduced unless both the systolic and diastolic values are lowered.

Marked reduction in blood pressure is considered as a drop of 80 mm. systolic and 25 mm. diastolic, or more.

Reduction of blood pressure to normal is considered as a drop to, or lower than, 130 mm. systolic and 90 mm. diastolic for patients up to the age of 40. After the age of 40 the drop must be to, or lower than, 150 mm. systolic and 100 mm. diastolic.

Changes in ocular fundi are evaluated by the department of ophthalmology. Improvement of the pathologic vessel changes, in the number of hemorrhages and exudates, of angiospasm and of papilledema is noted only when the change is beyond dispute. All fundi with equivocal changes are regarded as unchanged. Cases in which papilledema disappeared after operation have been given special attention. In addition the Keith-Wagener-Craig classification is used.

Urine concentration is regarded as normal if the patient is able to concentrate to a specific gravity of 1.029 or higher after thirty-eight hours without water, on a dry diet. During the past year, because of inconvenience of this test to the patient, a short concentration test has been substituted in which the normal value is considered to be 1.026 following eighteen hours without food or fluids. In both tests a change in specific gravity of three points or more is deemed necessary in order to be considered significant.

Urea clearance is considered normal if the values of the test averaged 75 per cent or higher. A change of 15 per cent is considered significant.

Cardiac size is determined by the teleoroentgenogram. Fifteen per cent above the predicted normal cardiac area is taken as evidence of enlargement. A change of 10 per cent or more is considered significant. All teleoroentgenographic measurements have been checked by orthodiagram.

Electrocardiograms are evaluated by the cardiologists on the degree of axis deviation and T wave changes. Each postoperative reading has been compared with the one taken preoperatively.

Symptomatology is, by necessity, evaluated from the patient's own statement. An attempt is always made to have all information as to changes in symptoms offered voluntarily by the patient.

Incapacitation is judged on the basis of the amount of work the patient was able to do immediately prior to operation as compared with his working ability before the onset of any incapacitation. Postoperative changes are judged on a similar basis.

In each instance the evaluation in every phase of the investigation has been made with the cooperation of the respective participating specialist. This approach has seemed, as nearly as possible, to avoid all individual prejudice. In the data presented it will be noted that in certain phases the proportion of cases without pertinent information may seem high. The primary reason is that whenever it has seemed apparent that the available data were incomplete or possibly inaccurate they have been deleted, even though such data indicated favorable results.

PREOPERATIVE STATISTICS

The 350 patients included in this study were operated on consecutively from November 1938 to September 1939. The technic of operation as described was used exclusively, and the operation was performed in each case by the same surgeon (M. M. P.). In tables 1 to 9 the preoperative observations are presented and discussed.

Approximately an equal percentage of males and females were operated on (table 1).

Ninety-three per cent of the patients were 30 years of age or older, with 50 per cent in the fifth decade (table 2).

(a) Due directly to hypertension.....	77
(b) Due to other causes.....	5
(c) No data	13
Operative mortality	(3.4%)

The blood pressure levels indicate a marked degree of hypertension in these patients. The average level is 218/133. Sixty-five per cent have systolic pressures above 210 mm. and 77 per cent have diastolic pressures above 125 mm. (table 3). These figures become even more significant when it is realized that these pressures were usually taken in the hospital with the patient on

bed rest and, commonly, following strict medical treatment over an extended period of time.

In the majority of cases the symptoms present (table 4) were severe. In the order of frequency they were occipital headache, headache elsewhere, increased nervousness and irritability, ease of fatigue, urinary frequency and nocturia, dizziness, dulness of mental processes, dyspnea, blurring of vision, nausea and vomiting, hemiplegia.

Exact information as to incapacitation (table 5) was available in 299 cases. It is significant that in 56 per cent of the cases studied incapacitation was either complete or marked, another indication that the hypertension level of the group was high.

Exact information as to the preoperative condition of the fundi (table 6) was not available in only five cases. It is significant that the hypertension was of severity sufficient to cause fundus changes in 97 per cent of the cases and that of these 56 per cent showed hemorrhages and exudates or papilledema.

Exact information as to fundusoscopic examination (table 7) was not available in five cases. It is significant that 70 per cent of the cases studied were in groups 3 and 4, i. e. showed, according to the authors of the classification, a marked severity of the hypertensive process and a very poor prognosis.

TABLE 11.—Distribution of Follow-Up Studies of 350 Cases According to Operative Year

Year of Operation	Number of Patients	Dead Before 9 Mos.	Cases Studied 9 Mos. or More Postoperatively (Including Deaths After 9 Mos.)	Cases with No Data in Any Phase (Including Deaths After 9 Mos.)
1933.....	1	..	1	..
1934.....	32	8	24	..
1935.....	62	7	54	1
1936.....	59	11	46	2
1937.....	93	10	83	..
1938.....	59	4	55	..
1939.....	44	4	39	1
Totals.....	350	44	302	4

Acceptable data were obtained on electrocardiographic examination in 222 cases, and on teleoroentgenographic measurement in 215 cases (table 8). Cardiac damage was indicated in about 60 per cent of the cases and enlargement in nearly 58 per cent. It is significant that the average percentage of enlargement above predicted normal was 35.

Exact information on urine concentration (table 9) was not available in sixteen cases and on urea clearance in eleven cases. Renal damage, as measured by urine concentration, occurred in 84 per cent of the cases, the extent indicated by the low average figure of 1.023.

Urea clearance was diminished in only 44 per cent. In these cases, however, the average value of 51 per cent indicates that the damage to the kidneys was fairly severe.

In summary of the preoperative observations in 350 cases it can be said that the hypertension (averaging 218/133) of the whole group was high. This fact is confirmed by the high percentage of severe ocular fundus changes (70 per cent in Keith-Wagoner-Craig groups 3 and 4) and of renal and cardiac damage. Almost all the patients (98 per cent) had symptoms sufficiently severe to cause complaint. In 39 per cent incapacitation was complete.

POSTOPERATIVE STATISTICS

Of the 350 patients operated on for hypertension approximately 65 per cent have been reexamined postoperatively in the clinics of the University Hospital and

34 per cent have had acceptable data forwarded by their local physician or hospital. Only four patients (1 per cent) have not presented information in at least one phase.

The data collected cover a time period of approximately seven years. No case has been included that has not had at least a nine months postoperative period.

TABLE 12.—Blood Pressure

	Number	Per Cent
Cases studied 9 months or later postoperatively (including deaths).....	290	100
Reduced (more than 40 mm. systolic and 15 mm. diastolic).....	149	51.4
Unchanged.....	134	46.2
Increased (more than 10 mm. systolic and 5 mm. diastolic).....	7	2.4
Cases with no data or dead before 9 months postoperatively.....	60	

If the sixty patients concerning whom no data were obtained or who died before nine months are considered as unchanged or worse, the percentage of patients with significantly reduced blood pressure in the whole group of 350 cases becomes 42.6.

This was deemed necessary to obviate the criticism that improvement was only temporary following a major operative procedure. The majority of patients have been reexamined more than once, and frequently at yearly postoperative intervals.

In evaluating the results of the operation those patients who have died subsequent to nine months after operation (obviously the poorest results) have been included in the complications.

Statistics are presented for each separate phase of the postoperative examination. Each phase is dealt with by two methods: first, a summary is given of the best results recorded at any one examination made nine months or more after operation, regardless of the exact postoperative interval; second, a table is presented which demonstrates the results by postoperative years.

No selection of cases was made. All who were able to return did so. More difficulty was encountered in getting the well patient who was working full time, and who had no complaints, to return than the sick patient, who was more than willing to take advantage of the opportunity of the gratis examination.

TABLE 13.—Analysis of Patients with Significantly Reduced Blood Pressure

	Number	Per Cent
Number of cases studied.....	149	100
Reduced to normal..... (130/90 for ages 20 to 40) (150/100 for ages 40 to 70)	56	37.5
Markedly reduced (but not to normal)..... (More than 80 mm. systolic and 25 mm. diastolic)	15	10.1
Reduced (but not markedly or to normal)..... (More than 40 mm. systolic and 15 mm. diastolic)	78	52.4

Thus, of those cases in which there was significantly reduced blood pressure 47.6 per cent were reduced to normal, markedly reduced or both.

All except 1 per cent of the cases have been studied in one or more phases postoperatively (table 10). The operative mortality was 3.4 per cent. Further statistical study of the deaths appears in a separate section later.

CLINICAL RESULTS OF SPLANCHNICECTOMY

No cases have been included (table 11) that have not been studied nine months or more from the time of operation. It is seen that seventy-eight cases have been studied more than five years and 196 cases for more than three years. With this wide spread of postoperative information it will be possible to show that the effects of the operation are not temporary.

Only 2.4 per cent of the 290 cases in which reliable postoperative information was obtained (table 12) showed a steady increase in blood pressure. It is obvious, therefore, that the majority of those patients who subsequently died had, at least at one examination, a blood pressure that was either improved or unchanged; otherwise the percentage would be much higher. It is only fair, however, to assume that the forty-four patients who died before nine months had no decrease in blood pressure. To be absolutely fair the sixteen patients on whom no data were obtained are also considered to be worse, although they undoubtedly were distributed in the same fashion as the others. Thus the absolute minimum of cases showing a significant reduction in blood pressure becomes, as noted, 42.6 per cent. Table 12 offers no information as to what period after nine months postoperatively the reduction occurred or whether it was maintained.

period of time without relief of either symptoms or high blood pressure. The operation was, then, a court of last appeal.

Table 14 is a demonstration of maintenance of the results of splanchnicectomy over a period of years. A sufficient number of the patients operated on were able to return for one or more check-up examinations through the years to show that reduction in blood pressure, once attained, persists. It is of equal importance to note that there was no significant increase in the percentage of patients in whom the blood pressure grew worse. It should be remembered that these statistics include check-up examinations of patients who subsequently died.

It may be assumed that if a patient had a significantly reduced blood pressure at, for example, the fifth year check-up the reduction had been maintained over that period. It is seen, as in the summary of check-up

TABLE 14.—Blood Pressure per Postoperative Year and Analysis of Patients with Significantly Reduced Blood Pressure per Postoperative Year

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)
Total patients studied (including deaths after 9 mos.).....	202	135	105	48	37	7	1
Blood pressure increased.....	3%	4%	4%	6%	5%
Blood pressure unchanged.....	33%	50%	40%	38%	49%	37%
Blood pressure reduced.....	44%	46%	50%	56%	46%	43%	100%
Analysis of reduced blood pressures.....	89	62	51	27	17	3	1
Reduced to normal..... (130/90 for ages 20 to 40; 150/100 for ages 40 to 70)	19%	34%	40%	26%	24%	33%
Markedly reduced (80 mm. systolic and 25 mm. diastolic, but not to normal)	20%	16%	18%	7%	24%	33%	100%
Reduced (40 mm. systolic and 15 mm. diastolic, but not markedly or to normal)	61%	50%	42%	67%	52%	33%

The arbitrarily chosen criteria (table 13) for "normal," "markedly reduced" and "reduced" blood pressures are obviously open to criticism. They were established only after much discussion and collaboration with well qualified observers in the field of hypertension, and then only for the purpose of simplifying the data. It is felt, however, that since the postoperative pressures were all taken with the patients ambulatory and under a considerable mental and physical strain, as compared to the preoperative readings when the patients had usually been on bed rest, the reductions are of true significance. Thus, as already noted, nearly 50 per cent of the patients who had reduced blood pressures showed a drop to normal, a marked reduction or both.

TABLE 15.—Age Distribution Correlated with Postoperative Blood Pressures

Number of cases studied 9 months or more postoperatively (including deaths)	Total Cases Studied			
Age at Time of Operation	Total Cases Studied	Reduced	Unchanged	Increased
10 to 19 years.....	1	1 (100%)		
20 to 29 years.....	18	14 (78%)	4 (22%)	
30 to 39 years.....	74	38 (51.4%)	35 (47.3%)	1 (1.3%)
40 to 49 years.....	150	74 (49.3%)	71 (47.3%)	5 (3.3%)
50 to 59 years.....	46	22 (48%)	23 (50%)	1 (2%)
60 years plus.....	1	1 (100%)		
Totals.....	290	149 (51.4%)	134 (46.2%)	7 (2.4%)

No other form of therapy as yet reported has shown as great a percentage of cases in which the blood pressure has been reduced to this extent.

This fact becomes even more significant when it is realized that the majority of these patients had been thoroughly treated by medical means over an extended

examinations showing the best results (tables 12 and 13), approximately 50 per cent of the patients show a reduction in blood pressure no matter whether the postoperative period was one or five years. Obviously the total number studied yearly reduces as the number operated on that number of years ago grows smaller.

TABLE 16.—Eyeground Changes

Total patients studied preoperatively and postoperatively..... 219			
Postoperative Result			
Preoperative Status	Improved	Unchanged	Worse
Normal eyegrounds..... 10	10 (100%)
Abnormal eyegrounds..... 209			
(a) Abnormal vessels only..... 102	50 (49%)	44 (43%)	8 (8%)
(b) Abnormal vessels plus hemorrhages and exudates..... 65	57 (88%)	6 (9%)	2 (3%)
(c) Papilledema..... 42	38 (91%)	4 (9%)	
	7 (17%) diminished		
	31 (74%) absent		

In analyzing those patients with reduced pressures it becomes clear that the degree of reduction, i. e. markedly reduced, reduced to normal or both, is also maintained throughout the postoperative years.

In table 15 the remarkable consistency of the percentage distributions is seen again. Surprisingly enough there is little evidence that older patients have a poorer prognosis as to the result of splanchnicectomy than do relatively younger patients. The best prognosis for reduction in blood pressure is in the age group from 10 to 29 years (78 per cent). After this age no significant difference is seen in the percentage with reduced pressure (always in the neighborhood of 50 per cent of the cases studied).

Table 16 indicates in each case studied nine months or more postoperatively the most favorable effect of the operation on the fundus oculi at any one examination.

It is significant that only ten patients of the 219 with fundusoscopic examinations both preoperatively and postoperatively showed a steady progression of the damage to the fundi, whereas 145 patients showed definite improvement regardless of the degree of damage before operation.

One of the most remarkable results of the operation occurred in the forty-two cases in which papilledema was present on preoperative examination. Of these patients thirty-one, or 74 per cent, showed complete disappearance of the edema on one or more postoperative examinations. Seventeen per cent showed diminution in the edema, 9 per cent remained unchanged and none grew steadily worse. Again it must be remembered that patients who subsequently died were included in these statistics.

65 to 100 per cent. In other words, the disappearance of the edema, when it occurred, was not a temporary effect since the percentage was approximately the same no matter what year the patient returned for his reexamination.

Of the 219 patients studied (table 18) both preoperatively and postoperatively (nine months or more after operation) only ten patients, or 4 per cent, had normal fundi preoperatively, and only sixty-three patients, or 29 per cent, showed the milder changes of groups 1 and 2.

The greatest number (147, or 67 per cent) had the advanced changes of groups 3 and 4, i. e. angiospasm or papilledema or both. Yet it was in the latter groups that the greatest improvement occurred as the result of operation. Thus 80 per cent of those who had group 3 preoperatively showed improvement on at least one examination postoperatively and, as shown in table 16, 91 per cent of group 4 showed improvement. Again it

TABLE 17.—Fundus Changes per Postoperative Year

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)
Total patients studied (including deaths after 9 mos.).....	136	91	72	38	23	6	1
Abnormal preoperatively							
Abnormal vessels only preoperatively.....	65	46	41	22	13	2
Postoperatively partially improved.....	43%	43%	61%	41%	61%
Postoperatively unchanged.....	48%	46%	46%	45%	31%	100%
Postoperatively worse.....	9%	9%	3%	14%	8%
Abnormal vessels plus hemorrhages and exudates preoperatively.....	37	30	16	7	5	2
Postoperatively partially improved.....	86%	80%	87.5%	71%	80%	50%
Postoperatively unchanged.....	14%	13%	12.5%	29%
Postoperatively worse.....	7%	20%	50%
Papilledema.....	26	14	13	7	5	2	1
Postoperatively absent.....	73%	65%	85%	100%	100%	100%	100%
Postoperatively partially improved.....	12%	28%	15%
Postoperatively unchanged.....	15%	7%
Postoperatively worse.....
Normal preoperatively.....	8	4	2	2
Postoperatively continues normal.....	100%	75%	100%	100%
Postoperatively worse.....	25%

Criticism could be made of the results recorded in table 16 on the ground that the results were only temporary and were not maintained. The table makes such criticism untenable, since it can be seen that the percentages, whether indicating good or bad results, remain relatively the same throughout the postoperative years.

TABLE 18.—Eyegrounds (Keith-Wagener-Craig Classification)

Preoperative Status		Postoperative Status		
		Improved	Unchanged	Worse
Total patients studied preoperatively and postoperatively.....		219		
Abnormal eyegrounds 209				
Group 1.....	13	1 (7%)	10 (78%)	2 (15%)
Group 2.....	50	22 (44%)	25 (50%)	3 (6%)
Group 3.....	105	84 (80%)	15 (15%)	5 (5%)
Group 4.....	42	7 (17%)	4 (9%)
Normal eyegrounds... 10		(absent) 31 (74%)	10 (100%)

Thus, about 45 per cent of the patients who had abnormal vessels only, i. e. showed sclerosis or angiospasm or both, maintained partial improvement throughout. Similarly, approximately 80 per cent of those with abnormal vessels, hemorrhages and exudates demonstrated a maintenance of improvement.

It is significant that the percentage of patients who had complete disappearance of papilledema following operation ranged through the postoperative years from

should be noted that of the latter group 74 per cent had complete disappearance of their papilledema at one or more examinations.

In a subsequent paper, now being prepared, it will be shown that the prognosis following splanchnicectomy for patients of groups 3 and 4 is far better than that given by the authors of this classification for the same groups treated only by medical means.

Once again (table 19), as in table 17, it is seen that improvement in eyegrounds is not a temporary effect of splanchnicectomy but rather that the percentages remain remarkably constant no matter what the year of check-up. Also it is again demonstrated that the greatest percentage of improvement occurs in those with the most serious damage to the fundi—i. e. in groups 3 and 4, and that this improvement is maintained proportionally throughout the years. It should be kept in mind that these statistics include, as has already been pointed out, the postoperative examinations of those patients who subsequently died; in other words, the cases with the poorest results.

The average heart size of the 105 patients (table 21) before operation was +18 per cent. Following operation, on at least one examination nine months or more postoperatively, the average heart size was reduced to 8.9 per cent.

It is significant that of the fifty patients who had hearts enlarged before operation 50 per cent returned to normal postoperatively and 14 per cent were partially improved. Only 4 per cent grew steadily worse.

Ninety-three per cent of the patients with normal heart size preoperatively remained within normal limits postoperatively.

preoperatively had an abnormal recording postoperatively.

The significant finding is that only five cases out of 127 demonstrated steadily increasing cardiac damage as measured by electrocardiogram.

The arrest in cardiac damage as measured by the electrocardiogram (table 23) was not a temporary effect

TABLE 19.—*Fundus Changes per Postoperative Year (Keith-Wagener-Craig Classification)*

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)
Total patients studied.....	136	94	72	38	23	6	1
Abnormal preoperatively							
Group 1	8	5	4	2	4	1
Postoperatively partially improved.....	1 (12.5%)	1 (25%)	1 (25%)

Postoperatively papilledema partially improved.....	3 (12%)	4 (28%)	2 (15%)
Postoperatively papilledema unchanged	4 (15%)	1 (7%)
Normal preoperatively	8	4	2	2
Postoperatively continues normal.....	8 (100%)	3 (75%)	2 (100%)	2 (100%)
Postoperatively worse	1 (25%)

TABLE 20.—*Heart Size per Postoperative Year*

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)
Total patients studied (including deaths after 9 mos.)	65	43	30	12	8	2
Heart enlarged preoperatively.....	30	24	13	8	6	1
Postoperatively normal.....	53%	29%	39%	50%	17%	100%
Postoperatively improved	7%	38%	15%	33%
Postoperatively unchanged	37%	29%	46%	50%	50%
Postoperatively further enlarged	3%	4%
Heart normal size preoperatively.....	35	19	17	4	2	1
Postoperatively continues normal	94%	93%	82%	100%	100%	100%
Postoperatively enlarged	6%	5%	8%

Diminution in heart size postoperatively was not a temporary effect of splanchnicectomy (table 20). Thus there is relatively constant distribution of the percentages no matter at what postoperative period the check-up examination was made.

Of seventy-three patients who had abnormal electrocardiograms before operation (table 22) 29 per cent

of splanchnicectomy. The percentages of the patients at each yearly check-up are relatively constant no matter the postoperative time interval. The marked increase

Heart size normal preoperatively, 53 cases.....	93%	7%

* A change of 10 per cent is considered significant.

became normal, 25 per cent were partially improved and 41 per cent remained unchanged. Only one patient out of fifty-four having a normal electrocardiogram

at the sixth year check-up is probably apparent (only three cases studied) rather than real.

Urea clearance determinations were made in 189 cases (table 25) before operation and at least once nine months or more postoperatively. Only 7 per cent of those with preoperatively abnormal values and 13 per cent of those with preoperatively normal values showed a steady decrease in renal function postoperatively. It is of importance to note that 51 per cent of the sixty-

nine cases showing decreased renal function before operation returned to normal or were partially improved postoperatively.

Table 24 would indicate that improvement in renal function as measured by urea clearance is not a temporary result of splanchnicectomy but persists in an almost constant percentage of cases over a long postoperative period. Similarly the percentages of those whose renal function grew worse following operation also remains nearly constant instead of increasing through the years as would be expected had the patients not been operated on.

Urine concentration tests were made in 208 cases (table 26) both preoperatively and postoperatively (at least once nine months or more after operation). Of

demonstrated by the consistency of the percentages showing improvement or return to normal throughout the postoperative years. Poorest results are seen in those patients who had normal concentrating ability preoperatively.

Of 284 patients 277 (98 per cent) complained of symptoms due to hypertension. Of these 86 per cent stated, on at least one examination nine months or more postoperatively, that their symptoms had either completely disappeared or were improved. Only 3 per cent were worse. Of the seven patients who had no symptoms before operation only one developed persistent symptoms. Deducting a possible psychotherapeutic effect, it still remains obvious that the majority of patients benefited markedly from the operation.

those who had decreased concentrating ability, 27 per cent returned to normal after operation and an additional 17 per cent were partially improved, making a total of 44 per cent improved.

It should be explained that the concentration test was shortened to eighteen hours during the last year of the study. It seems probable that the higher percentage of patients failing to show improvement in this

Complete or partial relief of the symptoms was maintained, as shown by the relative consistency of the percentages over a long period of time (table 28). It is

TABLE 25.—*Renal Function*

Urea Clearance

Normal, 36 cases..... (Long test: 1.029 plus) (Short test: 1.026 plus)	23 (64%)	13 (36%)

important to note the low percentages of those who remained unchanged or who grew worse.

It is obvious from these large percentages showing complete relief or partial improvement that many of the patients did not have a corresponding diminution in blood pressure. Many of the patients had blood pressures unchanged by operation. To them, however, the relief of symptoms, usually headache, was of vital importance. The answer to this apparent paradox is not

available at present. Research is being carried on by one of us (W. W. W.) relative to the physiology of cerebrospinal fluid pressure relationships in an attempt to explain why, following operation, so many patients receive persistent symptomatic relief from their headaches even though their blood pressure continues unchanged or goes even higher.

The statistics in table 30 indicate one of the most important results of splanchnicectomy. To the patient who must earn his living the ability to return to gainful occupation is of primary importance. Thus, of eighty-four patients who were completely incapacitated before operation 51 per cent had returned to full-time work at the time of at least one examination nine months or more postoperatively; 23 per cent had returned to part-time occupation.

percentages are significantly greater than could be expected for patients treated by medical means alone. They become even more significant when the preoperative observations presented in tables 1 to 10 are reviewed, indicating the marked degree of hypertension and the extensive systemic damage present in the majority of these patients before operation.

Wagener and Keith in a recent review of 219 cases of hypertension treated by medical means alone found a survival of only 9 per cent after five to nine years. In our series approximately 50 per cent have survived five years or longer. A paper is now being prepared which will show that the degree of hypertension in our cases as indicated by fundusoscopic examination was of comparable severity to that of the cases collected by these authors.

TABLE 27.—Urine Concentration per Postoperative Year

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)

Postoperatively improved	67%	59%	47%	49%	33%	29%
Postoperatively unchanged	11.5%	9%	8%	9%	8%
Postoperatively worse	0.5%	4%	4%	5%	6%
Symptoms absent preoperatively.....	5	3	1	2
Postoperatively unchanged	100%	67%	100%	50%
Postoperatively present	33%	50%

Of even greater significance is the fact that only fifteen of the 244 patients having adequate data on this phase showed a steady increase in their incapacitation. By far the majority showed a complete absence or partial improvement of this symptom.

It is clearly demonstrated in table 31 from the consistently high percentages of those patients, preoperatively incapacitated, who were able, after operation, to carry on full-time work that the effects of splanchnicectomy are not temporary. Thus, for example, 62 per cent of the patients, previously incapacitated, who were studied five years after operation were back at full time

It should be noted, as stated in table 32, that operative deaths, deaths due to causes other than hypertension, and cases in which no data could be obtained are all calculated statistically to give the absolute minimal survival percentages.

TABLE 30.—Incapacitation

work, and an additional 24 per cent were partially improved. The purely economic value of the operation to these patients was obviously very great.

The percentages of survivals according to year of operation are presented in table 32. We believe these

OPERATIVE AND POSTOPERATIVE DEATH STATISTICS

Out of the total number of 350 patients studied, on whom splanchnicectomy was performed, 107 patients died subsequently over a period of nearly seven years. Twelve of these were operative deaths, i. e. death occurred before they left the hospital. Seventy-seven are known to have died subsequently from a cause directly attributable to hypertension. Five are known

to have died from causes other than hypertension. Thirteen are known to be dead but the cause of death is unknown.

The operative mortality attendant on splanchnicectomy was 3.4 per cent. Of the twelve operative deaths ten patients were males and two females. One patient died on the operating table, probably of cerebral embolus. Four patients died immediately after operation (within eight hours), two of these of acute cardiac failure, one of cerebral hemorrhage and one of acute cerebral edema, of unknown etiology. The remaining seven patients died from one to twenty-five days after operation. Three of these died from cerebral hemorrhage, one from myocardial infarction (possibly occurring just before operation), one from pontile thrombosis, one from either coronary occlusion or pulmonary embolus, and one from lobular pneumonia with fibrinopurulent mediastinitis. It is interesting to note that only one patient died of thrombosis of the cerebral vessels, a contingency that would be expected to occur much more often, owing to the marked drop of blood

Data on subjective relief of symptoms were available for eighty-two patients of the total of ninety-five who died subsequent to operation. Following discharge from the hospital and up to the terminal illness, 11 per cent of these patients received complete relief from symptoms, 61 per cent received partial relief, 20 per cent were unchanged and only 6 per cent grew steadily worse. In other words 72 per cent of the patients received either complete or partial relief of their symptoms following operation regardless of the postoperative interval before death or the duration of their terminal illness.

Seventy-five patients died nine months or more following operation. Of these, prior to their terminal illnesses, 23 per cent had significant reduction in blood pressure on at least one examination, 2 per cent had reduction to normal, 63 per cent were unchanged and 12 per cent grew steadily worse.

It is of interest to note that the average postoperative survival period (exclusive of the operative deaths) was nineteen months.

TABLE 31.—*Incapacitation per Postoperative Year*

	First Year (9 to 18 Mos.)	Second Year (18 to 30 Mos.)	Third Year (30 to 42 Mos.)	Fourth Year (42 to 54 Mos.)	Fifth Year (54 to 66 Mos.)	Sixth Year (66 to 78 Mos.)	Seventh Year (78 to 90 Mos.)
Total patients studied (including deaths after 9 mos.).....	171	112	95	43	34	8	1
Incapacitation present preoperatively.....	134	86	81	36	29	8	1
Postoperatively absent	40%	59%	63%	56%	62%	87.5%	100%
Postoperatively partially improved	39%	26%	26%	30%	24%
Postoperatively unchanged	16%	12%	10%	14%	7%	12.5%
Postoperatively worse	5%	3%	2%	7%
Incapacitation absent preoperatively.....	37	26	14	7	5
Postoperatively continues absent	92%	81%	79%	86%	100%
Postoperatively present	8%	19%	21%	14%

pressure which occurs frequently during and immediately after operation.

The sex distribution of mortality is extremely interesting. Far more males died following operation than did

TABLE 32.—*Survival*

Year of Operation	Patients Operated On	Years After Operation	Patients Living	Per Cent Living	No Data
1933.....	1	7	1	100	..
1934.....	32	6	13	40.6	..
1935.....	62	5	37	59.5	1
1936.....	59	4	31	54.2	1
1937.....	93	3	70	75.3	..
1937.....	59	2	50	84.7	..
1938.....	59	1	38	64.4	1
1939 to September..	44	1	38	86.4	1
	350		250	77.7	3

These figures include twelve patients who died as the result of operation and at least five patients dead from causes other than hypertension. The three patients on whom no data were obtained are also calculated as dead.

females. Thus ten males had operative deaths and only two females. Subsequently sixty-four males died (39 per cent of the total males operated on) as against thirty-one females (17 per cent of the total females operated on).

Causes of death in the eighty-two cases with available data were thirty-one due to cerebrovascular accident, twenty-nine to cardiac failure, twenty-one to renal failure and five to causes other than hypertension. (Note: The discrepancy in the total number of cases is due to the fact that four cases were diagnosed as "cardiorenal failure" and hence were included in both categories.)

SUMMARY

Three hundred and fifty consecutive cases of hypertension with operation by bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy have been studied over a period of nearly seven years.

From table 33 it must be concluded that the operation of bilateral supradiaphragmatic splanchnicectomy

TABLE 33.—*Summary of Results of Splanchnicectomy: Percentage of Cases Studied Showing Improvement (From Nine Months to Seven Years After Operation) **

	Per Cent
Blood pressure	11.7
Reduced to normal.....	7.6
Markedly reduced (but not to normal).....	51.4
Total cases significantly reduced.....	59.0
General disability	86.6
Symptoms improved	55.5
Complete recovery incapacitation.....	81.3
Total cases with improvement incapacitation.....	81.3
Eye grounds	73.5
Disappearance of papilledema, when present.....	69.4
Total cases with improvement.....	69.4
Heart	64
Heart size diminished.....	51.4
Electrocardiogram improved	51.4
Renal function	52.2
Urea clearance improved.....	41.8
Urine concentration improved.....	41.8

* Statistics include those patients who showed improvement but who subsequently died.

and lower dorsal sympathetic ganglionectomy is of great value in the treatment of hypertension.

Of the patients studied 86.6 per cent had postoperative relief of major symptoms, especially headache, 81.3

per cent had improvement or complete relief of incapacitation and 51.4 per cent with adequate postoperative data had a significant reduction in blood pressure. Approximately one half of these patients had pressures reduced to normal or markedly reduced.

Improvement in ophthalmologic, cardiac and renal status following operation varied from 45 per cent to 70 per cent of the cases studied.

Prognosis is much more favorable in females than in males.

The most favorable results are obtained in the age group before 30. Following this period the age of the patient appears to be of minor importance as far as the result of operation is concerned.

Far advanced fundus changes, i. e. marked angiospasm and papilledema, are not contraindications to the operation.

The operative mortality is low (3.4 per cent) and no specific ill effects are attendant on the operation.

Finally, no other form of therapy, whether medical or surgical, has as yet been reported which offers as good results in patients suffering from hypertension of an equal degree of severity. Furthermore, these results are not temporary but continue over a period of years.

The conclusion is reached that the surgical treatment of hypertension by bilateral supradiaphragmatic splanchnicectomy and lower dorsal sympathetic ganglionectomy offers a better prognosis in cases of severe hypertension than any other form of therapy as yet reported.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

"TWIN CONTROL" HEAVY DUTY CAUTERY SET, "SINGLE CONTROL" CAUTERY SET AND "SIMPLIFIED CONTROL" CAUTERY SET ACCEPTABLE

Manufacturer: National Electric Instrument Company, Inc., 36-06 Forty-Second Avenue, Long Island City, N. Y.

The Cautery Sets submitted by the National Electric Instrument Company, Inc., consist of the following: "Single Control" Cautery Set designed to operate the lighter cautery tips manufactured by the firm (Nos. 1 to 7) and two larger units, the "Twin Control" Heavy Duty Cautery Set and the "Simplified Control" Cautery Set, designed to operate the heavier tips as well as the lighter ones.

According to information supplied by the firm, the heating elements of the cautery electrodes are made of "Nichrome" and are silver soldered into the shanks. Molded shank separators provide for insulation and rigidity.

The cautery pistol is molded of a boilable material known as "Neicomold" and a button momentary type of control switch, as well as a trigger lock for more lengthy cautery procedures. All internal contacts are of phosphor bronze and copper. The rubber-covered cautery pistol conductor cable is composed of two conductors of No. 13 copper, made up of 120 strands of No. 34 copper wire.

"Simplified Control" Cautery Set.

The transformers are of split primary windings. This construction is said to result in more efficient heat dissipation. The molded transformer housings provide efficient insulation and each of the terminals of the metal transformer is insulated from the metal panels by means of fiber or bakelite washers and bushings.

The Council's clinical investigation of the apparatus revealed that it gave satisfactory service. The cautery blades, which are of several sizes, can be heated from a dull red to almost white heat and retain this heat well when applied to the tissues; they do not cool down too rapidly to be effective. For cauterization within cavities, the instrument is accompanied by a light which is regulated from the instrument box itself.

The following results were obtained from physical tests performed in the Council's laboratory.

The "Twin Control" Heavy Duty Cautery Set was run for one hour, a No. 9 electrode and cautery light being used as load. The electrode was immersed in water to keep it from melting. The final temperature by the thermometer method was 95 C. and by the resistance method was 91.7 C. The input was 110 volts and 15 watts.

The "Single Control" Cautery Set was run for one-half hour, a No. 2 electrode immersed in water being used as a load. The final temperature by the thermometer method was 105 C. and by the resistance method 91.7 C. The input was 110 volts and 10 watts.

The Council voted to accept the "Twin Control" Heavy Duty Cautery Set, the "Single Control" Cautery Set and the "Simplified Control" Cautery Set for inclusion on its list of accepted devices.

MONTGOMERY WARD S-1 SUNLAMP ACCEPTABLE

Distributor: Montgomery Ward & Co., Chicago.

The Montgomery Ward S-1 Sunlamp, manufactured by the General Electric Company, produces ultraviolet radiation within the limits of the standards set by the Council for devices using the term "Sunlamp," which require that the energy of wavelengths shorter than and including 2,800 angstroms shall not exceed 1 per cent of the total energy of wavelengths between 2,804 and 3,132 angstroms. The wavelengths fall in the spectral region of low erythematogenic action and render the sunlamp suitable for unsupervised use by the layman.

The Mazda Sunlight Lamp Type S-1 is mounted in a reflector on an adjustable support and is a combination of tungsten electrodes in parallel with a tungsten filament. These are enclosed in a special glass bulb along with a little pool of mercury. The current first flows only through the filament but, as the temperature increases, the mercury vaporizes and an arc is formed between the ends of the tungsten electrodes. The process requires only a few seconds, although a few minutes is required for the lamp to begin radiating ultraviolet energy at its maximum efficiency. The mercury arc between the electrodes produces the major portion of the effective ultraviolet radiation. The result of the combination produces radiations in the visible and the infra-red as well as in the ultraviolet zones. The bulb is made of Pyrex glass, which absorbs most of the radiation in the ultraviolet region shorter than approximately 2,800 angstrom units.

The lamp operates only on alternating current; type S-1 requires an input of 450 watts. The lamp stands are equipped with special transformers in the base for the purpose of securing the proper voltage, since the S-1 bulbs do not fit in the ordinary lamp socket.

The Montgomery Ward S-1 Sunlamp generates 50 micro-watts per square centimeter at a distance of 45 inches from the rim of the reflector. A minimum perceptible erythema may be produced at a distance of 45 inches in twenty minutes on the average untanned skin.

The Council voted to accept the Montgomery Ward S-1 Sunlamp for inclusion on its list of accepted devices.

Montgomery Ward S-1 Sunlamp.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.

PAUL NICHOLAS LEECH, Secretary.

PURIFIED PROTEIN DERIVATIVE OF TUBERCULIN

Action on Name

Dr. Esmond R. Long inquired of the Council some time ago whether or not the name Purified Protein Derivative would be acceptable to the Council on Pharmacy and Chemistry as a designation for the purified protein principle of tuberculin. The Council voted that it would recognize the name Purified Protein Derivative of Tuberculin with the understanding that the initials P. P. D., which are widely used colloquially, will not be used in official designation of the product, as on packages or circulars.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

AMINOPHYLLINE (See New and Nonofficial Remedies, 1940, p. 555).

The following dosage forms have been accepted:

Tablets Aminophylline, 0.1 Gm. (1½ grains).

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Ampule Solution Aminophylline, 0.48 Gm., 2 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Ampule Solution Aminophylline, 0.24 Gm., 10 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Tablets Aminophyllin 0.1 Gm. (1½ grains).

Prepared by The Smith-Dorsey Company, Lincoln, Neb.

ATABRINE di-HYDROCHLORIDE.—Chinacrin Dihydrochloride.—The di-hydrochloride of 3-chloro-7-methoxy-9-(1-methyl-4-diethyl-amino)butylamino acridine.—

Actions and Uses.—Atabrine di-hydrochloride destroys the asexual forms of *Plasmodium vivax* and *P. malariae*, but the crescents of *P. falciparum* are more resistant. It does not induce hemolysis or cause damage to the liver or circulatory system when used therapeutically. It may cause epigastric distress and cramps, but it is of low toxicity when administered orally. The spleen of chronic malaria is not affected by atabrine di-hydrochloride but the acutely enlarged spleen yields, though more slowly, than to quinine. Its relative antimalarial value compared to that of quinine is much debated. It is claimed to act more rapidly and to require a shorter period of treatment. It does not induce symptoms of cinchonism, and it may be used during pregnancy. Its prophylactic value appears to be about equal to that of quinine. It is absorbed readily from the intestine and is excreted slowly in the urine and feces. While it is sometimes injected intramuscularly or even intravenously in cases of severe malarial infection when oral administration is not feasible, the intravenous injection is dangerous; the injections must be made very slowly. (See report of Field, J. W.; Niven, J. C., and Hodgkin, E. P.: Prevention of Malaria in Field by Use of Quinine and Atebrin (Atabrine); Experiments in Clinical Prophylaxis, Bull. Health Organ., League of Nations 6:236 [April] 1937.)

Dosage.—Oral. Adults: 0.1 Gm. (1½ grains) three times daily for five days. Children of 1 to 4 years: 0.05 Gm. (¾

grain) twice daily for five days or once daily for eight days, crushed and suspended in honey or syrup. Children of 4 to 8 years: 0.1 Gm. (1½ grains) twice daily for five days or once daily for eight days. Children over 8 years: Dosage like that of adults.

Prophylactic Dose: Adults: 0.2 Gm. (3 grains) twice weekly, or 0.05 Gm. (¾ grain) daily. Children: 0.05 Gm. (¾ grain) every other day.

The technic of the intramuscular or intravenous administration must be learned before the method is used. Details will be found in the circulars of manufacturers and in various publications.

Manufactured by the Winthrop Chemical Company, Inc., New York. U. S. patent 2,113,357 (April 5, 1938; expires 1955). U. S. trademark 302,473.

Ampules Atabrine di-Hydrochloride Powder 0.2 Gm. with Ampules, 10 cc. size, Sterile Distilled Water.

Tablets Atabrine di-Hydrochloride (Sugar Coated) 0.1 Gm. (1½ grains).

Tablets Atabrine di-Hydrochloride 0.1 Gm. (1½ grains).

Tablets Atabrine di-Hydrochloride 0.05 Gm. (¾ grain).

Atabrine di-hydrochloride occurs as an odorless, orange-yellow, bitter tasting, crystalline powder, containing two molecules of water of crystallization; it melts with decomposition between 245 and 247°C. It is soluble in water and slightly soluble in acetone, ether and benzene. Aqueous solutions of atabrine di-hydrochloride are colored yellow and exhibit yellow-green fluorescence.

Dissolve about 25 mg. of atabrine di-hydrochloride in 2 cc. of sulfuric acid, cover the yellow solution obtained with 0.5 cc. of nitric acid; a dark red color develops in the zone of contact and, on shaking, the solution turns red with loss of fluorescence.

Dissolve 1 Gm. of atabrine di-hydrochloride in 50 cc. of water. To a 5 cc. portion add 1 cc. of dilute ammonia water; an oily, yellow precipitate results. Add 5 cc. of amyl alcohol to the mixture and shake the test tube; the amyl alcohol layer contains the free base, atabrine.

To the first of four separate 5 cc. portions of the solution add 1 cc. of mercury bichloride solution; to the second portion add 1 cc. of potassium iodide solution; to the third portion add 1 cc. of ammonium thiocyanate solution; and to the fourth portion add 1 cc. of potassium dichromate solution; a yellow precipitate is produced in each mixture. To another 5 cc. portion add 2 drops of nitric acid and 5 drops of silver nitrate solution; a white precipitate forms, soluble in excess ammonia water. To another 5 cc. portion add 1 cc. of barium chloride solution; no turbidity results.

The *pn* of a solution made by dissolving 1 Gm. of atabrine di-hydrochloride, accurately weighed, in boiled and cooled distilled water sufficient to make 100 cc. of solution is between 4.5 and 4.9 at 25°C.

Dry about 1 Gm. of atabrine di-hydrochloride, accurately weighed, to constant weight at 100°C.: the loss in weight should not be less than 5.5 per cent nor more than 7.5 per cent.

Incinerate 1 Gm. of atabrine di-hydrochloride; the ash is negligible.

Transfer 1 Gm. of atabrine di-hydrochloride, accurately weighed, to a 100 cc. calibrated flask and add 50 cc. of water. When the salt has dissolved, add slowly 4.5 cc. of normal sodium hydroxide solution, mix with swirling (avoid air bubble entrapment) and fill to the mark with water. Filter the solution into a dry 250 cc. beaker, and add about 0.3 Gm. of halogen-free decolorizing charcoal. Stir the mixture and allow it to stand for five minutes; then filter through a dry paper. Reject the first 25 cc. of the colorless filtrate, take 50 cc. of the remainder, and titrate as directed under volumetric method 1 in Official and Tentative Methods of Analysis of the Official Agricultural Chemists, edition 4, 1935, page 131. The calculated content of hydrochloric acid should not be less than 14.1 per cent nor more than 14.6 per cent.

Transfer about 0.25 Gm. of atabrine di-hydrochloride, accurately weighed, to a 100 cc. calibrated flask, add 10 cc. of water and 26 cc. of a solution made by dissolving 26 Gm. of sodium acetate and 26 cc. of 40 per cent acetic acid in sufficient water to make a total of 100 cc. To the solution in the calibrated flask add 50 cc. of tenth-normal potassium dichromate and water to the mark. Avoid air bubble entrapment. Mix thoroughly and filter the solution through a dry paper, rejecting the first 15 cc. of the filtrate. Transfer 50 cc. of the filtrate to a glass-stoppered Erlenmeyer flask, add 13 cc. of hydrochloric acid and 20 cc. of potassium iodide test solution. Stopper the flask and mix the contents by swirling gently. Allow the mixture to stand in the dark for two minutes and titrate the liberated iodine with tenth-normal sodium thiosulfate. Each cubic centimeter of tenth-normal potassium dichromate used is equivalent to 0.007881 Gm. of anhydrous atabrine di-hydrochloride. Add 3 mg. to the weight found to compensate for inherent errors of the method. The content of anhydrous atabrine di-hydrochloride should be not less than 92.5 per cent or more than 94.5 per cent.

PROCAINE HYDROCHLORIDE-ABBOTT (See New and Nonofficial Remedies, 1940, p. 81).

The following additional dosage forms have been accepted:

Ampoules Procaine Hydrochloride 1%, W/V, 1½ cc.: Each 1½ cc. contains procaine hydrochloride-U. S. P. 0.015 Gm., sodium chloride and chemically pure water to make an isotonic solution.

Ampoules Procaine Hydrochloride 1%-Epinephrine 1:50,000 Solution, 2 cc.: Each 2 cc. contains procaine hydrochloride-U. S. P. 0.02 Gm. (½ grain), epinephrine 0.00004 Gm. (¼,600 grain) and sodium bisulfite 0.002 Gm. in isotonic solution.

BOVINE TETANUS ANTITOXIN (See New and Nonofficial Remedies, 1940, p. 419).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia.

"Lyovac" Tetanus Antitoxin (Bovine).—An antitoxin derived from the blood serum of cattle immunized against the toxin of *Bacillus tetani* (Clostridium tetani). It is packaged by the "Lyovac" process, which consists essentially of rapid freezing at a temperature far below the freezing point, together with rapid dehydration under high vacuum without

melting or fusing of the original frozen substance. Marketed in packages containing one ampule vial of lyophilized antitoxin representing 1,500 units and a 3 cc. ampule vial containing distilled water for restoration of the antitoxin, with a 1 cc. ampule vial of normal bovine serum (1:10 dilution) for sensitivity tests; and in packages containing one ampule vial of lyophilized antitoxin representing 10,000 units and a 20 cc. ampule vial containing distilled water for restoration of the antitoxin, with a 1 cc. ampule vial of normal bovine serum (1:10 dilution) for sensitivity tests.

PHYSIOLOGICAL SOLUTION OF SODIUM CHLORIDE (See New and Nonofficial Remedies, 1940, p. 379).

The following dosage form has been accepted:

Ampoule Physiological Solution of Sodium Chloride, 50 cc.
Prepared by Endo Products, Inc., Richmond Hill, N. Y.

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1940, p. 486).

The following dosage forms have been accepted:

Ampoule Solution Sodium Morrhuate 5% with Benzyl Alcohol 2%, 2 cc.: Each cubic centimeter contains sodium morrhuate 0.05 Gm. and benzyl alcohol 0.02 Gm. in aqueous solution.

Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

Ampoule Solution Sodium Morrhuate 5% with Benzyl Alcohol 2%, 5 cc.: Each cubic centimeter contains sodium morrhuate 0.05 Gm. and benzyl alcohol 0.02 Gm. in aqueous solution.

Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

Solution Sodium Morrhuate 5% with Benzyl Alcohol 2%, 25 cc. Bottle: Each cubic centimeter contains sodium morrhuate 0.05 Gm. and benzyl alcohol 0.02 Gm. in aqueous solution.

Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

ASCORBIC ACID (See New and Nonofficial Remedies, 1940, p. 530).

The following dosage forms have been accepted:

Tablets Ascorbic Acid, 15 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

Tablets Ascorbic Acid, 25 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

Tablets Ascorbic Acid, 50 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

Tablets Ascorbic Acid, 100 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

NICOTINIC ACID (See New and Nonofficial Remedies, 1940, p. 524).

The following dosage forms have been accepted:

Tablets Nicotinic Acid, 20 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

Tablets Nicotinic Acid, 50 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

Tablets Nicotinic Acid, 100 mg.

Prepared by the Upjohn Company, Kalamazoo, Mich.

MERCURIC SUCCINIMIDE (See New and Nonofficial Remedies, 1940, p. 338).

Endo Products, Inc., Richmond Hill, N. Y.

Ampoules Mercury Succinimide-Endo, 0.01 Gm. (1/10 grain), 1 cc.

SODIUM THIOSULFATE (See New and Nonofficial Remedies, 1940, p. 488).

The following dosage forms have been accepted:

Ampoules Sodium Thiosulfate Solution-Endo, 0.5 Gm., 5 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

Ampoules Sodium Thiosulfate Solution-Endo, 1.0 Gm., 10 cc.

Prepared by Endo Products, Inc., Richmond Hill, N. Y.

SULFANILAMIDE (See New and Nonofficial Remedies, 1940, p. 489).

The following dosage forms have been accepted:

Tablets Sulfanilamide-Endo, 5 grains.

Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

Tablets Sulfanilamide-Endo, 7 1/2 grains.

Prepared by Endo Products, Inc., Richmond Hill, N. Y. No U. S. patent or trademark.

QUINIDINE SULFATE (See New and Nonofficial Remedies, 1940, p. 395).

The following dosage form has been accepted:

Capsules Quinidine Sulfate, 0.2 Gm. (3 grains).

Prepared by the Abbott Laboratories, North Chicago, Ill.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

Yeast of High Vitamin B₁ Content for Bakers

The Council has encouraged the restorative addition of essential vitamins and minerals to processed foods as one method of facilitating the selection of a diet that is adequate for good health. A pound loaf of ordinary white bread provides about 50 to 100 international units of vitamin B₁. A pound loaf of whole wheat bread (meaning the genuine whole wheat bread) provides about 450 international units of vitamin B₁. The thiamine content of white bread may be increased in a variety of ways. One method consists in the use of high vitamin B₁ potency yeast in place of the ordinary yeast that is used for leavening the dough.

The following product has been given consideration by the Council and found acceptable as a preparation for increasing the nutritive value of ordinary bread with respect to vitamin B₁:

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295).

Standard Brands Incorporated, New York.

FLEISCHMANN'S HI-B YEAST FOR BAKERS, a variety of baker's yeast, *Saccharomyces cerevisiae*, cultured to yield a product of high vitamin B₁ content. The yeast is distributed in compressed cakes, weighing 1 pound and containing 30,000 international units of vitamin B₁, for use by bakers as an ingredient of bread doughs. Before shipment every batch of yeast is tested for vitamin content and baking strength and also is examined bacteriologically.

Analysis (submitted by manufacturer).—Moisture 70.0%, total solids 30.0%, ash 1.8%, fat (ether extract) 0.5%, protein (N \times 6.25) 15.5%, glycogen 9.5%, yeast fiber 2.7%, carbohydrates other than yeast fiber (by difference) 9.5%.

Assays show that the product uniformly contains not less than 30,000 international units of vitamin B₁ to the pound. Other vitamins of the B complex natural to yeast also are present. Used in the amount of 2 per cent in a bread formula (2 pounds of compressed yeast to 100 pounds of flour) the resulting bread contains approximately 450 international units of vitamin B₁ to the pound loaf.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156).

Gerber Products Co., Fremont, Mich.

GERBER BRAND STRAINED PEAR AND PINEAPPLE.

Analysis (submitted by manufacturer).—Moisture 81.5%, total solids 18.5%, ash 0.3%, protein (N \times 6.25) 0.3%, fats (ether extract) 0.3%, crude fiber 0.7%, carbohydrates other than crude fiber (by difference) 16.9%, calcium¹ (Ca) 0.0096%, phosphorus (P) 0.0078%, iron (Fe) 0.0019%.²

Calories.—0.72 per gram; 20.4 per ounce.

H. J. Heinz Company, Pittsburgh.

HEINZ BRAND STRAINED TOMATO SOUP, a canned condensed strained cooked mixture of tomatoes, carrots, potatoes, celery, sucrose, rice, soy bean flour, dried whey and sodium chloride.

Analysis (submitted by manufacturer).—Moisture 83.7%, total solids 16.3%, ash 1.3%, sodium chloride (NaCl) 0.8%, fat (ether extract) 0.1%, protein (N \times 6.25) 2.0%, crude fiber 1.6%, carbohydrates other than crude fiber (by difference) 10.8%, total sugar 9.4%, calcium (Ca) 0.0221%, phosphorus (P) 0.039%, iron (Fe) 0.0009%, copper (Cu) 0.00021%, acidity as citric acid 0.49%, pH 4.4.

Protocols of biologic assay submitted by manufacturer (1940) showed that this product contains 23.17 international units of vitamin A, 0.262 international unit of vitamin B₁, and 0.505 Sherman-Hourquin unit of riboflavin per gram; 656.8, 7.4 and 14.3 per ounce. Report of chemical titration (1940) showed that the product contained 5.4 international units of vitamin C per gram, 153 per ounce.

Calories.—0.54 per gram; 15 per ounce.

UNCLASSIFIED AND MISCELLANEOUS FOODS, PEANUT BUTTER (See Accepted Foods, 1939, p. 381).

Rose Field Packing Company, Ltd., Alameda, Calif.

SKIIPPY BRAND PEANUT BUTTER CHUNK STYLE, regular peanut butter to which one-eighth inch particles of roasted peanuts have been added, sugar and sodium chloride.

Analysis (submitted by manufacturer).—Moisture 0.4%, total solids 99.6%, ash 3.1%, fat (ether extract) 49.1%, protein (N \times 6.25) 30.8%, crude fiber 0.9%, carbohydrates other than crude fiber (by difference) 11.3%.

Calories.—6.3 per gram; 179 per ounce.

1. Calcium was determined by the method of Meloche, W. V.; Clifcorn, L. E., and Griem, W. B.: Determination of Calcium in Mineral Mixtures. J. A. O. A. C. 18: 240 (May) 1935.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, NOVEMBER 30, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

FULL TIME TEACHING IN CLINICAL MEDICINE

In 1900 there were some 155 medical colleges in the United States. Today the number of four year medical schools is sixty-six. In those days medical schools included some for which preparation was merely high school graduation, a few which required some university education. Today the majority of medical students have had at least three years of college education before entering on the study of medicine. Thus has come about a tremendous advancement of standards. No doubt the first great impetus toward that advancement came when the American Medical Association established the Council on Medical Education and Hospitals and began publishing regularly the statistics on medical schools and on licensing boards. However, the situation was dramatized when the first report by Abraham Flexner was published under the auspices of the Carnegie Foundation for the Advancement of Teaching. This publication served to call public attention to the neces-

sity for improvement and thereby gave to the American Medical Association the type of support that it needed in its drive for educational advancement. The work here mentioned is probably the best known contribution of Abraham Flexner. However, his autobiography, recently published,¹ serves to remind us of many other valuable contributions to the civilization of our times.

At the age of 17 Abraham Flexner was sent to Johns Hopkins University. It becomes obvious, as one follows through Mr. Flexner's career, that Johns Hopkins and what he saw later in Germany influenced him tremendously and through him came to have a significant effect on all American medical education. He developed the concept that German medical education was sound precisely where American medical education was deficient, referring particularly to adequate entrance requirements which were enforced, close relationships between the laboratories and clinics, teachers who were professors and not practicing physicians, and a high place for research. He found some minor defects in German medical education but he does not emphasize these greatly.

If there is any one aspect of Mr. Flexner's recommendations that has agitated American medicine in recent years, it is the question of full-time versus part-time clinical teaching. In his twelfth chapter Mr. Flexner tells the story of the introduction of the full-time system. According to Mr. Flexner, he himself is not to be credited with the authorship of what is called the full-time scheme. He relates that the suggestion came to him from Dr. Mall, eminent professor of embryology and anatomy in Johns Hopkins University Medical School, when Dr. Mall said "If the school could get a sum of approximately a million dollars, in my judgment there is only one thing that we ought to do with it—use every penny of its income for the purpose of placing upon a salary basis the heads and assistants in the leading clinical departments, doing for them what the school did for the underlying medical sciences when it was started." The scheme, however, did not originate with Dr. Mall but is attributed to the great Leipzig physiologist Ludwig, who one day, so Mall said, remarked to him that sooner or later teaching and research in clinical medicine and surgery would have to be organized on the same basis as teaching and research in anatomy and pathology. It is asserted that both of these had once been in the hands of practicing physicians and neither had prospered as they should until they commanded the full time and strength of the men engaged in their teaching and cultivation. Mr. Flexner reports that this scheme was unanimously endorsed by the laboratory men but there was a rift among the clinicians, and that the opinion of Dr. William Osler, then at Oxford, was adverse. Since the establishment of the full-time plan it has been a constant subject of debate among medical educators. In the United States today our medical schools vary from

1. Flexner, Abraham: I Remember, New York, Simon and Schuster, 1940.

some which have a majority of full-time teachers in the clinical branches to one of our leading medical schools which still has none. No doubt an impartial evaluation of our educational system would recognize certain aspects of full-time teaching which are desirable but would also recognize some of the defects which the introduction of this system has created.

One of the extraordinary phenomena of the entrance of the full-time teacher into medical education has been a sort of group attitude in questions concerning medical economics. Here is perhaps a problem to which the sociologist or psychologist might well give special attention. In questions concerning the costs and distribution of medical service, in problems of political and governmental character that have agitated the medical profession in recent years, there has failed to be a community of interest. Part or full-time teachers in the medical schools have not in general supported the elected representatives of the medical profession. True, there have been on both sides individuals who have departed from the herd. In general, the alignments have been as here suggested.

As the leaders of one group have sought for federal funds to aid the medical schools, practitioners of medicine have asserted that they were concerned primarily with their own rather than with the public good. As the practitioners of medicine have sought to maintain independence from governmental control, the teaching groups have charged that they were protecting their professional interest in the patient's pocketbook and have not been concerned with the public good. Obviously the economic situation of the schools, and of the private practitioners as well, in these times of stress has brought about extraordinary conditions in which the true issues may occasionally have been lost to sight. The problem of educating physicians for the care of the sick and the increasing costs of medical education, associated with university control, may have some responsibility for this situation.

Incidentally, the answer to the problem of medical care cannot lie in state provision of medical care to be given under the auspices of medical educational institutions. The mere fact that there exist so many states in which there are institutions for medical education, that there are such wide areas in which educational institutions are not available, the fact that educational institutions tend to multiply in large centers where a mass of so-called clinical material is available for teaching purposes, would indicate that the chief purpose of the educational institution is to educate and that the chief purpose of the physician is the care of the sick.

Unfortunately the assumption of these attitudes seems to result in a loss of interest by the practicing medical profession in the whole problem of medical education. The physicians of large cities have become interested because there is obviously a social, professional and educational advantage in being associated with a teaching institution. Physicians far removed,

however, from teaching centers express disinterest in many instances simply because they have felt that the teaching institutions were much more concerned with their own prestige and advancement than with the primary problems of medical practice. The extension of the functions of medical education to the field of graduate education of the practicing physician would unquestionably bring these physicians again within the fold of medical education.

MECHANISM OF EXPERIMENTAL RENAL HYPERTENSION

From a study of the hemodynamics of the perfused isolated canine kidney, Kohlstaedt and Page¹ of the Lilly Laboratory for Clinical Research, Indianapolis, have formulated a definite theory as to the method of production of arterial hypertension, subsequent to experimental renal ischemia.

Six years ago Goldblatt and his co-workers² of the Institute of Pathology, Western Reserve University, proved that in dogs renal ischemia caused by bilateral compression of the renal arteries is almost invariably followed by a definite and persistent elevation in systolic blood pressure. Since this secondary hypertension is not prevented by preliminary denervation to the kidneys, it seemed logical to assume that it is due to some unknown retention product or internal secretion from the kidneys. Transplantation of ischemic kidneys into normal dogs confirmed the so-called internal secretion theory. Much experimental and clinical evidence seems to indicate that renin may be the pathologic internal secretion responsible for this hypertension, even though it has not been shown to the satisfaction of most clinicians that renin is actually liberated by the ischemic kidney. Proof is made difficult by the fact that renin in itself is not a pressor substance and requires chemical activation to produce vasoconstriction.

In order to confirm the renin hypothesis, Kohlstaedt and Page perfused the isolated normal canine kidney with defibrinated blood under varying hemodynamic conditions. Venous blood samples drawn from these perfused kidneys were activated with renin complement and the resulting angiotonin titrated for pressor effects by pulsate perfusion through the isolated rabbit ear.

Excised normal canine kidney perfused under normal pulsate arterial pressure did not secrete renin into the venous blood. Venous blood collected at the beginning and the end of such perfusions showed no differences in vasoconstriction properties when complemented with renin activator. When the renal artery was partially clamped, however, and the resulting reduced blood flow continued for 100 or more minutes, the venous blood samples acquired vasoconstrictor properties. Renin secretion was not prevented by increasing the rate of perfusion flow to normal by increasing the per-

1. Kohlstaedt, K. G., and Page, I. H.: *J. Exper. Med.* 72:201 (Aug.) 1940.

fusion pressure. From this and from other hemodynamic tests the authors conclude that the essential cause of renin liberation is not changes in blood pressure or perfusion rate but reduced pulse pressure. Numerous investigators have shown that perfusion of isolated organs under constant pressure almost invariably leads to edema, a pulsate perfusion being necessary for normal tissue maintenance. Presumably a pulsate pressure is necessary for adequate interstitial lymph drainage.

Summarizing their experimental evidence, the Indianapolis clinicians formulate a definite theory. According to this theory, compression of the renal artery "leads to partial conversion of pulsate to continuous blood flow in the kidney with edema and anoxia of the cells of the tubules as the chief results. Increase in cellular membrane permeability follows and allows the liberation of the large renin molecule. Renin reacts with renin activator to produce angiotonin, which itself raises blood pressure and causes efferent glomerulin arteriolar constriction and further tubular anoxia. A vicious circle may be thus set up which results in sustained arterial hypertension."

While this pulse pressure theory will require experimental and clinical confirmation before it can be definitely accepted, it would seem to be the only definite theory thus far suggested to explain the physiologic mechanism of experimental renal hypertension. It is a provocative working hypothesis for further clinical research. The possible antigenic properties of homologous renin and angiotonin are now under investigation.

Current Comment

MR. MACFADDEN DISCUSSES ARMY MEDICAL SERVICE

In the current issue of *Liberty* Mr. Bernarr Macfadden, its publisher, signs an editorial in which he proposes that homeopaths, osteopaths, naturopaths and chiropractors be given a chance to demonstrate the value of their methods, using the soldiers of the American army as guinea pigs. He cites statistics to indicate that osteopaths lost only one fourth of 1 per cent of their patients from influenza in the 1918 epidemic and that doctors lost from 5 to 6 per cent. He says that osteopaths had a fatality record of 10 per cent for pneumonia as compared with a medical fatality record of 33 per cent. As for the chiropractors, Mr. Macfadden indicates that they claim even better records. Obviously the validity of such statistics is highly questionable, even taking into account the fact that anybody who gets sick enough gets a doctor and that therefore mortality rates would naturally be higher for the seriously sick than for people who are not seriously sick. Furthermore, there would also be a considerable amount of doubt as to the diagnoses made by incompletely and peculiarly trained cultists as contrasted with the scientific diagnoses made by physicians. People who diagnose in their patients diseases which do not exist find it easy to cure such cases. When a common cold is called influenza and

pneumonia, it is easy to claim a cure. Many a cold gets well without any treatment whatever. Mr. Macfadden complains, incidentally, that the soldiers overeat and that their work is not sufficient to take up their food intake. This generalization is made, of course, without the slightest knowledge on his part of just how much soldiers eat or of the considerable scientific attention that is being given to nutrition for American soldiers. Fortunately for the American soldier the medical corps is under the direction of competent officials, and the work of that department is, in turn, controlled by the general staff. No doubt these men realize their obligation to the young men who are under their care and will not permit themselves to be swayed by the extravagant claims of irresponsible cultists or by the distorted diatribes of Bernarr Macfadden.

ALCOHOL AND THIAMINE IN NUTRITION

The amount of food consumed by those who regularly drink alcohol in considerable quantities influences the development of the so-called alcoholic diseases. Once a full diet was thought to counteract toxic effects of alcohol, but now it is known that certain of these typical diseases—Korsakoff psychosis, alcoholic polyneuritis, pseudopellagra and some types of encephalopathia alcoholica—are real vitamin deficiencies. Fantus¹ has recently emphasized various obvious as well as more subtle factors influencing the thiamine intake; inadequate consumption of foods containing vitamin B₁ is plainly of importance and the statement is made that "chronic alcoholism is the most frequent predisposing factor in cases of severe involvement in Cook County Hospital," which situation is undoubtedly typical of other large centers. According to Jolliffe,² alcohol may contribute to nutritional deficiency disease by decreasing appetite as a result of its irritant action on the gastrointestinal mucosa, by interference with absorption, by substituting its "vitamin-free" calories for energy in the form of vitamin-containing food and by disturbing the ratio between metabolizable energy and thiamine. Only when the vitamin/calory ratio is maintained above a marginal value will there be freedom from subclinical or outspoken signs of deficiency; a diet can be rendered inadequate by either decreasing the vitamin intake or increasing the vitamin-free sources of calories. Jolliffe has shown that the rather narrow margin of safety in the modern American dietary with respect to adequacy of vitamin B₁ can be greatly decreased or largely erased by the consumption of alcohol, since the metabolism of the alcohol calories increases the need for thiamine which the alcohol itself cannot provide. Frequently the true etiology of the vitamin deficiency disease is obscured by naming the disease after the condition responsible for the increased demand for the vitamin as, for instance, "diabetic," "metabolic," "infectious," "gestational" or "gastrogenous" polyneuritis. Obviously a close relationship exists between energy metabolism and thiamine requirement.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

NEW ARMY HOSPITALS

New army hospitals are to be built in New Orleans, Savannah, Ga., and Hinesville, Ga., under the defense appropriation bill, according to *Modern Hospital*. The \$1,200,000 cantonment hospital planned for New Orleans will have a capacity of 1,000 beds and will be of the pavilion type, probably of temporary construction. It will be located in the New Orleans lake shore development along Lake Pontchartrain, according to present plans, and will be used to give treatment to men stationed at Camp Beauregard and other army establishments in that section of the country.

A hospital of from 150 to 200 beds has been approved for the airport in Savannah to provide for the 3,500 officers and men of the air corps stationed there. For the Savannah anti-aircraft area with six regiments, or about 15,000 men, an institution of from 600 to 800 beds will be constructed at Hinesville. The hospitals to be built in Georgia are expected to be replaced later by more substantial structures, since the Savannah and Savannah area army bases will be permanent.

CONFERENCE OF CORPS AREA SURGEONS

A meeting of corps area surgeons was held at the office of the surgeon general, U. S. Army, Washington, D. C., October 14-16, to discuss problems arising from the induction of the National Guard, expansion of the Army and induction of trainees. Major Gen. James C. Magee, surgeon general, presided. All corps area surgeons, except Col. Will L. Pyles of the Fifth Corps Area, as well as heads of divisions in the office of the surgeon general were present. Among other matters, it was decided to station a nurse at headquarters of each corps area to advise the corps area surgeon on matters affecting nurses, especially in connection with the procurement of 4,019 nurses within the next few months for active duty with the Army.

NATIONAL DEFENSE NIGHT IN HOLLYWOOD

The Hollywood Academy of Medicine devoted its meeting in the Hollywood Roosevelt Hotel, November 14, to a consideration of national defense. Dr. Roy Ledford, San Diego, discussed medical defense; other speakers were Capt. Frederic L. Conklin, M. C., U. S. Navy, chief, surgical service, U. S. Naval Hospital, San Diego; Lieut. Col. Harold V. Raycroft, M. C., U. S. Army, past surgeon, Fort McArthur; Lieut. Col. Dennis W. Sullivan, unit instructor, California National Guard, 160th; Lieut. Comdr. Roy J. Leutscher, M. C., U. S. Navy, chief, medical service, U. S. Naval Hospital, San Diego, and Major John F. Bohlender, M. C., U. S. Army, unit instructor for the medical corps reserve.

BULLETIN OF WAR MEDICINE

As a part of its contribution to medical preparedness, the Medical Research Council of Great Britain has made available a publication called the *Bulletin of War Medicine*, which is a collection of abstracts dealing with the handling of many military-medical affairs, taken from the available medical literature. The first number consists of 62 pages containing 109 abstracts. This Bulletin is available to American readers by addressing the British Library of Information, 50 Rockefeller Plaza, New York. The price is 75 cents per copy.

PUBLIC HEALTH OFFICERS ASSIGNED TO CAMPS

Nine officers of the U. S. Public Health Service have been assigned to the nine U. S. Army corps areas to act as liaison officers with the corps area surgeons especially in problems arising in extra-military areas. Environmental sanitation with emphasis on control of communicable diseases will be their chief responsibility, according to an announcement. The officers assigned are: Drs. Louis L. Williams, Walter T. Harrison, Frank V. Meriwether, Lon O. Weldon, Knox E. Miller, Albert E. Russell, Harry J. Warner, Joseph Bolten and Edgar W. Norris.

MEDICOMILITARY LECTURES IN PHILADELPHIA

A course of lectures on "Military Maxillofacial Surgery" began, November 18, at the Philadelphia County Medical Society Building under the auspices of the Philadelphia County medical and dental societies, the schools of dentistry of the University of Pennsylvania and Temple University and the W. W. Keen Chapter of the Association of Military Surgeons of the United States. The lectures were planned at the request of the surgeon general of the U. S. Army. The first in the series was given by Dr. Oscar V. Batson, professor of anatomy, University of Pennsylvania School of Medicine, and Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, on "Anatomy of the Face, Jaws and Neck in Relation to War Injuries."

The final lectures in the series presented during the fall by the Philadelphia County Medical Society were as follows:

Lieut.-Col. Asa M. Lehman, Medical Corps, U. S. Army, Noncombatant Military Hospitals and Medical Installations—Civilian Institution Sponsored Hospitals of the Army, November 14.

Dr. Frank W. Burge, The Tuberculosis Problem in the Mobilization of Military and Naval Personnel, November 21.

Lieut. Commander Nathaniel M. Levin, Medical Corps Reserve, U. S. Navy, War Injuries—Air and Food Passages, December 5.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

WAR DEPARTMENT

Following is a list of medical reserve corps officers who had been placed on extended active duty with the regular army by War Department order, Washington, D. C., up until November 8:

ABBAMONTE, Louis Walter, 1st Lieut., Norwich, N. Y.
 ABRAMS, Morris, 1st Lieut., Chicago.
 ADAMS, Eldridge Stevens, Lieut. Col., Washington, D. C.
 ADAMS, George Furman, 1st Lieut., San Francisco.
 AKIN, Robert Louis, 1st Lieut., Monterey, Tenn.
 ALBERTI, Vincent Samuel, 1st Lieut., New York.
 ALBUS, William R., Captain, Fort Sheridan, Ill.
 ALLEN, Robert Wilson, Captain, Keystone, S. D.
 ALLEN, Roy Johnson, 1st Lieut., Sumner, Iowa.
 ALLEN, Samuel, 1st Lieut., East Liverpool, Ohio.
 ALPER, Irwin Isidor, Captain, Ithaca, N. Y.
 AMES, Edward S., 1st Lieut., Forest Hills, N. Y.
 AMLIE, Paul Jones, 1st Lieut., Tripoli, Iowa.
 AMSTER, Milton William, Captain, Brooklyn.
 ANDERSON, John Leonard, Captain, Osceola, Iowa.
 ANDERSON, Edgar Emmet, Captain, Marysville, Kan.
 ANGELL, Howard Hathaway, 1st Lieut., Detroit.
 ANGELLA, Carl Louis, 1st Lieut., Roseville, Calif.
 APONTE, Pedro Rivera, Captain, Fajardo, P. R.
 ARNISTEAD, William Wilchia, Captain, Shreveport, La.
 ARNOLDI, Louis Bernhard, 1st Lieut., New Orleans.
 ARONOFF, Solomon, 1st Lieut., Hoboken, N. J.
 ASCHIER, David Samuel, 1st Lieut., Boston.
 ASHTON, Paul Louis, 1st Lieut., San Francisco.
 AUERBACH, Sidney, 1st Lieut., New York.
 AUSTER, Benjamin, 1st Lieut., Bronx, N. Y.
 AYNER, Saul Leighton, Captain, Savannah, Ga.
 AYERS, Robert Lawrence, 1st Lieut., Pennegrove, Calif.
 AZORIN, Louis Arthur, 1st Lieut., Omaha.
 BACH, Leo Francis, Captain, Mapleton, Minn.
 BADGER, Edward Bruce, Captain, Minneapolis.
 BAER, Erwin Jerome, 1st Lieut., Seattle.
 BAERS, Harry, 1st Lieut., St. Louis.
 BAIRD, Robert Desmond, Jr., 1st Lieut., Edwardsville, Ill.
 BALKO, Andrew John, Captain, El Paso, Texas.
 BALLWEG, Harry Albert, Captain, Brooklyn.
 BAMBACE, Felix Shelley, Captain, Spokane, Wash.
 BARBER, Herbert Gordon, 1st Lieut., Omaha.
 BARKS, Orville Leon, 1st Lieut., Groveland, Fla.
 BARRETT, Robert Syer, 1st Lieut., Hamlin, W. Va.
 BARTOLINI, Frank Joseph, 1st Lieut., Phillipsburg, N. J.
 BAXTER, Clarence Pennell, Lieut. Col., San Diego, Calif.
 BEATY, Charles Samuel, 1st Lieut., Cherokee, Okla.
 BECKER, Harry Gregory, Captain, Evanston, Ill.
 HEGLEY, Philip Jones, 1st Lieut., Hyden, Ky.
 BELL, Allan Brooks, 1st Lieut., Shelton, Wash.
 BELL, Herbert Joseph, Captain, Denver.
 BELL, Robert Stanton, 1st Lieut., Ollie, Iowa.
 BELZ, Joseph A., Captain, Baltimore.
 BENENSON, Abram S., 1st Lieut., East Rockaway, N. Y.
 BENNETT, Bruce Hardy, 1st Lieut., Washington, D. C.
 BENNETT, Webster William, 1st Lieut., Harrisburg, Pa.
 BENNETT, William Horace, 1st Lieut., Paris, Ark.
 BERG, Philip, Jr., 1st Lieut., Philadelphia.
 BERGMAN, Harold Hanford, 1st Lieut., Gillette, Wyo.
 BERLINER, Harry Morris, Captain, Bronx, N. Y.
 BIER, Robert Allen, Captain, Washington, D. C.
 BISKIND, Gerson Ravinson, 1st Lieut., San Francisco.
 BLACK, Benjamin Stephen, 1st Lieut., Rochester, N. Y.
 BLACKSOM, Berget Henri, Jr., 1st Lieut., Rockford, Ill.
 BLOEMENDAAL, Edwin G. J., Captain, Orange City, Iowa.
 BOBES, Solomon Subere, Captain, Wheeling, W. Va.
 BOCHIENEK, John Edward, 1st Lieut., Newark, N. J.
 BODEN, Worthey Carl, 1st Lieut., Davenport, Iowa.
 BOLTON, Ralph Daniel, 1st Lieut., Canton, Ohio.
 BONSIGNORE, Marco Romolo, 1st Lieut., Rochester, N. Y.
 BOROS, Harold Henry, 1st Lieut., Chicago.
 BOSLOW, Harold Meyer, 1st Lieut., Appalachia, Va.
 BOUCHER, Adore Louis, 1st Lieut., Denver.
 BOURIAND, Philip Ewing MacIntyre, 1st Lieut., Calumet, Mich.
 BOYDSTONE, Joseph Oscar, Captain, Hot Springs, Ark.
 BRADLEY, Harold John, 1st Lieut., Brevard, N. C.
 BRADY, Richard Randall, Captain, Tacoma, Wash.
 BRAMBLE, Russell Blaine, Captain, South San Francisco, Calif.
 BRENNER, William Rush, 1st Lieut., Bazine, Kan.
 BRESLIN, John Francis, Captain, Bridgeport, Pa.
 BRIGHT, Albert Seymour, 1st Lieut., Silver Spring, Md.
 BRIMSON, James Ashton, 1st Lieut., Welfare Island, N. Y.
 BRIN, Alfred Ross, 1st Lieut., Terrell, Texas.
 BRISTOL, Frank Ernest, Jr., 1st Lieut., Summit, N. J.
 BRITTON, Bryce Hill, Captain, El Paso, Texas.
 BROCKMAN, Sidney Clark, 1st Lieut., Louisville, Ky.
 BRODERICK, Thomas Aloysius, 1st Lieut., San Francisco.
 BROOKS, Robert Hancy, 1st Lieut., Celeste, Texas.
 BROTHNER, Robert Jacob, 1st Lieut., St. Paul.
 BROTMAN, Jacob H., Captain, Corsicana, Texas.
 BROWN, Charles Thomas, Captain, San Marcos, Texas.
 BROWN, John Edward, Jr., Captain, Blue Mountain, Miss.
 BROWN, Otto Richard, Captain, Los Angeles.
 BROWN, Raymond Milton, 1st Lieut., San Francisco.
 BROWN, Robert Andrew, Jr., 1st Lieut., Greenville, S. C.
 BRUNO, Nicholas Joseph, 1st Lieut., Stambaugh, Mich.
 BRUSSELL, Albert Sinai, Captain, St. Paul.
 BRUTON, Ogden Carr, Captain, Nashville, Tenn.
 BRYANT, Mason David, Jr., 1st Lieut., Lowell, Mass.
 BUCKHOLD, Wilbert William, 1st Lieut., Brandenburg, Ky.
 BUCKHOLTS, Walter Howell, Captain, Elephant Butte, N. M.
 BUERMANN, Henry, Jr., 1st Lieut., Maplewood, N. J.
 BURKS, Arthur Lynn, 1st Lieut., San Francisco.
 BURNETT, Jack Frost, 1st Lieut., Ennis, Texas.
 BURPEAU, William Purdy, Captain, East Orange, N. J.
 BURSTEIN, Henry Albert, Captain, Toledo, Ohio.
 BURTON, Horace French, 1st Lieut., East Tawas, Mich.
 BUSH, Glendon Joseph, 1st Lieut., Detroit.
 BUTMAN, Burton Brooker, 1st Lieut., Syracuse, N. Y.
 BLARS, Perry J. C., 1st Lieut., Lampasas, Texas.
 BYARS, Jerry J. C., 1st Lieut., Lampasas, Tex.
 CACCIATORE, Thomas Joseph, 1st Lieut., Brooklyn.
 CADA, Edward George, 1st Lieut., Berwyn, Ill.
 CALARCO, John Joseph, 1st Lieut., Jamaica, N. Y.
 CAMARDELLA, Ralph Andrew, 1st Lieut., Lynbrook, N. Y.
 CAMPBELL, Joseph Lester, Captain, Ulster, Pa.
 CANNON, Edward Gaine, Captain, Hope Mills, N. C.
 CALLAWAY, James Willis, Captain, La Jolla, Calif.
 CANTRELL, Roy Hammond, Captain, Dallas, Texas.
 CAPALBO, Sylvester Alfred, 1st Lieut., Philadelphia.
 CAPOLA, Michael Thomas, Jr., 1st Lieut., Philadelphia.
 CARDONA, Angel Antonio, Captain, Washington, D. C.
 CAROFIGLIO, Louis Edward, Captain, Chicago.
 CARROLL, Charles Thomas, 1st Lieut., Yonkers, N. Y.
 CASSEL, Melvin Alfred, 1st Lieut., St. Louis.
 CASSIDY, John M., Captain, Chandler, Okla.
 CAVENDER, Savino Walter, 1st Lieut., St. Louis.
 CHAMPION, Walton Thomas, 1st Lieut., Gillett, Ark.
 CLAGETT, Augustus Henry, Jr., Captain, Providence, R. I.
 CLAIBORNE, John Wallons, Jr., Captain, Fort Oglethorpe, Ga.
 CLARKE, Charles Luther, 1st Lieut., Memphis, Tenn.
 CLARKE, Lloyd Anton, 1st Lieut., Kenmore, N. Y.
 CLIFF, Arthur Edgar, Captain, Washington, D. C.
 CHAPPELL, Ewin Summers, 1st Lieut., Washington, D. C.
 COGAN, Leo Judas, Captain, Milwaukee.
 COHEN, Lawrence Jack, 1st Lieut., Baltimore.
 COHEN, Leon John, 1st Lieut., Bronx, N. Y.
 COLEMAN, William Richard, 1st Lieut., Torrington, Wyo.
 COLPOYS, William Patrick, Jr., 1st Lieut., Dorchester, Mass.
 COLQUITT, Alfred Olin, Jr., 1st Lieut., Spartansburg, S. C.
 COLUCCI, David Dominic, 1st Lieut., Rochester, N. Y.
 COLVIN, Paul Verlander, 1st Lieut., Longview, Texas.
 CONNER, Cooper Marion, 1st Lieut., Fort Worth, Texas.
 COONE, Herbert William, 1st Lieut., Providence, R. I.
 CORGILL, Donald Alton, 1st Lieut., Monticello, N. Y.
 COSTRINO, Joseph Alfred, 1st Lieut., St. Louis.
 CRAFTS, John Gardner Hale, Captain, San Francisco.
 CRAWFORD, James Marion, 1st Lieut., New Albany, Miss.
 CRUTCHER, Luke Fain, 1st Lieut., Los Angeles.
 CUMMING, Richard Cralle, Captain, Ocala, Fla.
 CURRIE, Daniel Smith, Jr., 1st Lieut., Parkton, N. C.
 CURTIS, Morris Williams, Captain, Williamsport, Pa.
 CUVILLIER, Louis Marshall, Jr., 1st Lieut., Washington, D. C.
 DAILEY, Jeremiah Aloysius, Captain, El Paso, Texas.
 D'ALFONSO, Anthony Daniel, 1st Lieut., Philadelphia.
 DAMERON, James Haden, Major, Livingston, Texas.
 DAMIAN, Julius Daniel, 1st Lieut., Washington, D. C.
 DANIELS, Elijah Robert, 1st Lieut., Orange, Calif.
 DANIELS, John Quincy Adams, Captain, Portland, Ore.
 DANISHEK, Emil Stephan, 1st Lieut., Seattle.
 DART, Merrill Oren, 1st Lieut., Denver.
 DATZ, Lewis Anthony, 1st Lieut., Pueblo, Colo.
 DAVENPORT, John Robert, Captain, Holdenville, Okla.
 DAVIDSON, Harold Jack, 1st Lieut., Tulsa, Okla.
 DAVIDSON, Morris, 1st Lieut., Elkhart, Ind.
 DAVIES, Dale Henley, 1st Lieut., Seattle.
 DAVIS, Elmer Louis, Captain, Floresville, Texas.
 DAVISON, Augustus Marion, 1st Lieut., Fayetteville, Ark.
 DEL GIUDICE, Amore, 1st Lieut., Waterbury, Vt.
 DELLINGER, Raiden Winfield, 1st Lieut., Rome, Ga.
 DETER, Dwight Meyer, Captain, Austin, Texas.
 DEUTSCH, Albert Leopold, 1st Lieut., Brooklyn.
 DeVAN, William Todd, II, 1st Lieut., Philadelphia.
 DeVITA, Jacob, 1st Lieut., Brooklyn.
 DeVITTORIO, Armond Anthony, 1st Lieut., Ridgeway, Pa.
 DIAMOND, Bernard Lee, 1st Lieut., Ann Arbor, Mich.
 DIAMOND, Max Myer, 1st Lieut., Galveston, Texas.
 DICKINSON, Louis Everett, Jr., 1st Lieut., Ravenna, Neb.
 DIEHL, Earl Henry, Captain, Dunedin, Fla.
 DIGANGI, Mariano Richard, 1st Lieut., Brooklyn.
 DILWORTH, Warren Miller, 1st Lieut., Omaha.
 DINES, George Louis, 1st Lieut., Caropolis, Pa.
 DISARIO, Anthony Ryham, 1st Lieut., Philadelphia.

WENTWORTH, John Hall, 1st Lieut., New Haven, Conn.
WEST, Jasper Daniel, Captain, Memphis, Tenn.
WEAVER, Emerson M. F., Captain, Lancaster, Pa.
WIELAND, Wesley William, 1st Lieut., Virginia Beach, Va.
WHITE, Raymond Leroy, 1st Lieut., New Plymouth, Ida.
WESTCOTT, Albert Goodwin, 1st Lieut., San Francisco.
WHISTLER, Carl William, 1st Lieut., El Paso, Texas.
WHITCOMB, Luther Myron, 1st Lieut., Carlisle, Pa.
WHITE, Edgar William, Lieut.-Colonel, New York.
WHITE, Fletcher Howard, 1st Lieut., Burlington, Vt.
WHITE, Gilbert William, Captain, East Prospect, Pa.
WHITE, Thomas Beeman, 1st Lieut., Plain Dealing, La.
WHITMAN, Joseph Jay, Captain, Cleveland.
WHITMER, Lysle Henderson, 1st Lieut., Wilton Junction, Iowa.
WILLIAMS, John Wyley, Captain, Oak Grove, Mo.
WILLIAMS, Russel I., 1st Lieut., Lincoln, Neb.
WILLIGER, Irwin Fox, 1st Lieut., South Harriman, Tenn.
WINGFIELD, William Lynn, 1st Lieut., Ashland, Va.
WOLF, Nathan, 1st Lieut., Baltimore.
WOLFE, Herbert S., Captain, New York.
WONG, James Sin Fook, Captain, Philadelphia.
WRIGHT, Burchard Eakin, Jr., Captain, Philadelphia.
WRIGHT, Garland Miller, 1st Lieut., Harrisonburg, Va.
WRIGHT, Jack McClellan, 1st Lieut., Stillwater, Okla.
WRIGHT, Thomas Rogers, 1st Lieut., El Paso, Texas.
WYLIE, John Thomas, Captain, Dallas, Texas.
YACHNIN, Samuel Cyril, Captain, Lyndhurst, N. J.
YOUNG, Charles Oran, 1st Lieut., San Pedro, Calif.
YOUNG, Richard Wallace, 1st Lieut., Baton Rouge, La.
YOVAISH, Walter, Captain, Germfask, Mich.
ZEFF, Charles, 1st Lieut., New York.
ZOX, Maurice Levi, 1st Lieut., Philadelphia.
ZWEIBEL, Leonard, 1st Lieut., Newark, N. J.

FOURTH CORPS AREA

The following medical reserve corps officers have been ordered to active duty by Fourth Corps Area Order since November 8. The Fourth Corps Area comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana.

ABRAM, Lewis E., 1st Lieut., Fitzgerald, Ga.
ARNOLD, Laurie J., Jr., 1st Lieut., Lake City, Fla.
ARP, Charles R., 1st Lieut., Atlanta, Ga.
ARTEAGA, Oliver, 1st Lieut., Atlanta, Ga., Camp Blanding, Fla.
BARFIELD, Hugh H., 1st Lieut., Atlanta, Ga.
BARNWELL, Edward H., Lieut. Col., Charleston County, S. C.
BERRY, John L., Captain, Miami, Fla., Savannah A. A. Firing Center, Savannah, Ga.
BICHARD, Phillip M., 1st Lieut., Orlando, Fla.
BLEICH, Jack K., Captain, Atlanta, Ga.
BUCKLEY, Madison H., 1st Lieut., Martin, Tenn., Camp Peay, Tullahoma, Tenn.
BURGE, Julius C., Jr., 1st Lieut., Black Mountain, N. C., Camp Peay, Tullahoma, Tenn.
CASTELLOW, William F., Captain, Americus, Ga.
CHEW, Nathaniel J., 1st Lieut., Bristol, Tenn.
COLLINS, Braswell E., 1st Lieut., Waycross, Ga., Camp Blanding, Fla.
CONNOR, John M., 1st Lieut., Panama City, Fla., Camp Blanding, Fla.
DUCKWELL, Fred M., 1st Lieut., Kingsport, Tenn.
EDELSON, Edmond K., 1st Lieut., New Orleans.
FARRAR, Turley, 1st Lieut., Memphis, Tenn.
FITZGERALD, Charles E., 1st Lieut., Farmville, N. C., Camp Beauregard, La.
GEESELYN, Lawrence E., 1st Lieut., Atlanta, Ga.
HALLOWAY, Charles E., 1st Lieut., Atlanta, Ga.
HARRELL, Henry L., Captain, Ocala, Fla.

ALLMAN, Sydney J., 1st Lieut., Mattapan, Mass.
FAGONE, Francis A., 1st Lieut., Portland, Maine.
FAMULARO, Nicholas A., Lieut., Jackman, Maine.
GORMAN, Richard J., Lieut., Winchendon, Mass.
HEELS, George E., Lieut., Cambridge, Mass.
NELSON, John A., Lieut., Augusta, Maine.
SHERMAN, Bernard I., Captain, Providence, R. I.
SHUMAN, Harold I., 1st Lieut., Brookline, Mass.
WILLSON, Allan T., Lieut., Farmington, N. H.

HARRISON, Albertus F., 1st Lieut., Florence, S. C., Savannah A. A. Firing Center, Savannah, Ga.
HOLLIDAY, Henry C., 1st Lieut., Athens, Ga.
HOUSTON, John L., 1st Lieut., Memphis, Tenn.
KENNEDY, Leon T., Captain, Winston-Salem, N. C.
KRONRAD, Lorenz, 1st Lieut., Columbia, S. C., Camp Beauregard, La.
LEVY, Tracy, 1st Lieut., New Orleans, Savannah A. A. Firing Center, Savannah, Ga.
MASON, George S., 1st Lieut., Lumberton, Miss.
McCORD, William M., 1st Lieut., New Orleans, Camp Beauregard, La.
McCRAVEY, Augustus, 1st Lieut., Whitestone, Ga.
McNABB, John T., 1st Lieut., Whitwell, Tenn., Savannah A. A. Firing Center, Savannah, Ga.
MUSE, William S., 1st Lieut., Knoxville, Tenn.
OWENS, Bennett G., Major, Valdosta, Ga., State Headquarters Selective Service, Atlanta, Ga.
PALMER, Clarence B., 1st Lieut., Covington, Ga.
PREAS, William G., Captain, Johnson City, Tenn.
ROBERTS, Louis C., 1st Lieut., Durham, N. C., Camp Peay, Tullahoma, Tenn.
SAMS, Frank H., 1st Lieut., Reynolds, Ga.
SAUNDERS, Joseph H., 1st Lieut., New Orleans, Meridian, Miss.
SELIGMAN, Ewing, Captain, Nashville, Tenn., Camp Shelby, Miss.
SIMS, Murphy M., 1st Lieut., Oxford, Miss., Camp Blanding, Fla.
SMITH, Phillip D., 1st Lieut., Knoxville, Tenn., Camp Shelby, Miss.
STATON, Leon R., 1st Lieut., Hayesville, N. C.
STOVALL, James T., Jr., 1st Lieut., Jefferson, Ga.
STROHMENGER, Frank J., 1st Lieut., Kingsport, Tenn.
SULLIVAN, Francis M., 1st Lieut., Atlanta, Ga., Fort Benning, Ga.
THARP, George W., Jr., 1st Lieut., Knoxville, Tenn., Fort McClellan, Ala.
WEINER, Harry, Captain, Birmingham, Ala., Camp Peay, Tullahoma, Tenn.
WEINSTEIN, Alfred A., Captain, Atlanta, Ga.
WYLIE, Paul E., 1st Lieut., Bemis, Tenn., Camp Peay, Tullahoma, Tenn.

YOUNG, John J., 1st Lieut., Natchitoches, La., Camp Shelby, Miss.
YUCKMAN, William, 1st Lieut., Quitman, Ga., Savannah A. A. Firing
Center, Savannah, Ga.
ZIEMAN, Alphonse H., 1st Lieut., Mobile, Ala., Camp Beauregard, La.

Orders Revoked

Orders have been revoked on the following named officers reported in previous report:

CARNEY, Henry M., Captain, Nashville, Tenn., Savannah A. A. Firing
Center, Savannah, Ga.
CRAIGHEAD, Claude C., 1st Lieut., Athens, La., Camp Blanding, Fla.
McCLARY, George R., 1st Lieut., Miami, Fla., Camp Peay, Tenn.

RAY, Emmett B., 1st Lieut., Kosciusko, Miss.
WEBB, John K., 1st Lieut., Columbia, S. C., 4th Division, Fort Benning,
Ga.
WILLIEN, Leon J., Captain, Knoxville, Tenn.

Orders Changed

Changes have been made in the station or effective date of orders in the following named officers:

PHILLIPS, James R., 1st Lieut., Baton Rouge, La., Camp Beauregard, La.
SCOTT, Wood H., 1st Lieut., Bonita, La., Fort McClellan, Ala.
WARSHAUER, Samuel E., 1st Lieut., Wilmington, N. C., Camp Shelby,
Miss.

FIFTH CORPS AREA

The following medical reserve corps officers had been ordered to active duty by the Fifth Corps Area Order up to and including midnight, November 8. The Fifth Corps Area comprises the states of Ohio, Indiana, Kentucky and West Virginia:

ALLEN, Chester H., Captain, Portsmouth, Ohio.
ARCHER, Maurice C., 1st Lieut., Medina, Ohio.
AYERS, Lloyd R., Captain, Beckley, W. Va.
BARNHART, John W., 1st Lieut., Clendenin, W. Va.
BAUHOF, Ned F., 1st Lieut., Canton, Ohio.
BEDINGER, Francis E., 1st Lieut., Walton, Ky.
BLOOMER, Richard S., 1st Lieut., Rockville, Ind.
BONNELL, George H., Jr., 1st Lieut., Worthington, Ohio.
BOOHER, Norman R., 1st Lieut., Indianapolis.
BOWSHIER, Robert E., 1st Lieut., Toledo, Ohio.
CARSON, James H., Captain, Martins Ferry, Ohio.
COLBERT, Morgan R., 1st Lieut., Louisville, Ky.
CONRAD, Harold A., Captain, Elkins, W. Va.
CELLIO, Lewis W., Captain, Carrollton, Ohio.
CRANSTON, Clyde J., Captain, Wakeman, Huron County, Ohio.
DAVIDSON, William D., Captain, Evansville, Ind.
DIETL, Ernest L., 1st Lieut., South Bend, Ind.
DILLARD, Harry K., 1st Lieut., Ashland, Ky.
DORROH, Glenn U., Captain, Columbus, Ohio.
DURKEE, Melvin S., 1st Lieut., Evansville, Ind.
EISNER, David G., 1st Lieut., Cleveland.
EVERETT, Clyde W., Captain, Cleveland.
FORD, Sylvester C., 1st Lieut., Cleveland.
GEIGER, Franklin R., 1st Lieut., Cincinnati.
GILLESPIE, Benjamin S., 1st Lieut., Tacoma, Ohio.
GITLIN, William A., 1st Lieut., Bluffton, Ind.
GRAU, Harry R., Captain, Cleveland.
GROVE, Thomas L., 1st Lieut., Huntington, W. Va.
HEWLETT, Thomas H., 1st Lieut., New Albany, Ind.
HOOVER, Reuben B., 1st Lieut., Columbus, Ohio.
KANNER, Irving F., 1st Lieut., Lexington, Ky.
KAPLAN, Ronald R., 1st Lieut., Cleveland Heights, Ohio.

KAUFFMAN, Nelson N., 1st Lieut., Indianapolis.
KILMER, John H., 1st Lieut., Fort Wayne, Ind.
LACOCK, Walter B., Captain, Columbus, Ohio.
LAMONICA, Leon L., 1st Lieut., Cleveland.
LEICHLITER, John W., Captain, Cincinnati.
LIPSCOMB, William N., Major, Lexington, Ky.
LOEB, William J., 1st Lieut., Cleveland Heights, Ohio.
LUND, Leonard C., 1st Lieut., Argos, Ind.
LYBROOK, William B., 1st Lieut., Galveston, Ind.
LYONS, Robert E., Jr., Captain, Bloomington, Ind.
LYTLE, Robert P., Captain, Cleveland.
MARCHANT, Clarence H., 1st Lieut., Bloomington, Ind.
MARCUS, Louis L., 1st Lieut., Toledo, Ohio.
MATSON, John W., 1st Lieut., Uhrichsville, Ohio.
McEWEN, James W., Captain, Terre Haute, Ind.
McLAUGHLIN, Calvin P., 1st Lieut., Pendleton, Ind.
MEILING, Richard L., 1st Lieut., Columbus, Ohio.
MISHKIN, Irving, Captain, Elkhart, Ind.
MOORE, Kenneth G., Captain, Fort Worth, Texas.
NORTHUP, Clarence E., II, 1st Lieut., Columbus, Ohio.
NOVACK, Benjamin F., 1st Lieut., East Chicago, Ind.
PEACOCK, Norman F., 1st Lieut., Crawfordsville, Ind.
PEASE, Phillip P., Captain, Chardon, Ohio.
PEBWORTH, James T., 1st Lieut., Indianapolis.
PICKAR, Daniel N., 1st Lieut., Wheeling, W. Va.
ROBBINS, James S., 1st Lieut., Mayfield, Ky.
RODENBERG, Elmer J., Captain, Columbus, Ohio.
ROUSH, Carl E., 1st Lieut., Cincinnati.
SHARP, John L., 1st Lieut., Crawfordsville, Ind.
STANLEY, John S., 1st Lieut., East Chicago, Ind.
STOREY, William R., 1st Lieut., Hobart, Ind.
TEMPLETON, Ames R., 1st Lieut., South Bend, Ind.
THOMAS, Morris C., Captain, Indianapolis.
THOMPSON, Roy H., Captain, Cleveland.
TOUPKIN, Jerome H., 1st Lieut., Charleston, W. Va.
WAGENAAR, Edward H., Captain, Shipshewana, Ind.
WELCH, Brent A., 1st Lieut., Sidney, Ohio.
WIER, James A., 1st Lieut., Evansville, Ind.
WILSON, Orley E., 1st Lieut., Elkhart, Ind.

SIXTH CORPS AREA

The following additional medical reserve corps officers had been ordered to extended active duty by Sixth Corps Area Order up to November 22. The Sixth Corps Area comprises the states of Wisconsin, Illinois and Michigan.

ASKWIG, LeRoy C., 1st Lieut., Detroit.
BENNETT, Keith F., Captain, Kalamazoo, Mich.
BENNETT, Sanford A., 1st Lieut., Detroit.
DANA, Harold M., 1st Lieut., Detroit.
FITZGERALD, Maurice D., Captain, Chicago.
GAYNES, Harvey E., 1st Lieut., Chicago.
GOLDIN, Morris I., 1st Lieut., Detroit.

GORDON, Harold L., 1st Lieut., Detroit.
GREENBERG, Morris Z., 1st Lieut., Detroit.
HAUSER, Maurice J., 1st Lieut., Chicago.
HIRSCHFELD, Alexander H., 1st Lieut., Ann Arbor, Mich.
JULIAR, Benjamin, 1st Lieut., Detroit.
KENNEDY, Donald J., 1st Lieut., Detroit.
KOON, William D., 1st Lieut., Grand Rapids, Mich.
LARIMORE, Granville W., 1st Lieut., Chicago.
LASSAR, Gilbert N., 1st Lieut., Springfield.
MALLER, Adolph M., 1st Lieut., Chicago.
QUARTON, Albert E., Jr., 1st Lieut., Ann Arbor, Mich.
RYGH, Edgar A., Captain, Highland Park, Ill.
SHINGLMAN, Willard E., Captain, Cicero, Ill.
SUGARMAN, Marcus H., 1st Lieut., Detroit.
WARNKE, Robert D., 1st Lieut., Detroit.

NINTH CORPS AREA

Following are the names of medical reserve corps officers ordered to extended active duty by Ninth Corps Area Order for the week ended November 16. The Ninth Corps Area comprises the states of Washington, Montana, Wyoming, Oregon, Nevada, Utah, California and Idaho.

BANKS, Gerald F., 1st Lieut., San Diego, Calif., Presidio of Monterey,
Calif.
BARNES, Norman J., 1st Lieut., Los Angeles, Fort MacArthur, Calif.
COZEN, Lewis N., Captain, Los Angeles, Fort Lewis, Wash.
DAVIS, Irving, Captain, San Francisco, Presidio of Monterey, Calif.
DONICH, George M., 1st Lieut., Butte, Mont., Fort Lewis, Wash.
GARDNER, Elsworth L., 1st Lieut., Eugene, Ore., Fort McDowell, Calif.
GOERKE, Lenor S., 1st Lieut., Woodland, Calif., With State Director
of Selective Service, State of California.
GROSSBLAT, Jacob, 1st Lieut., Los Angeles, Presidio of Monterey,
Calif.

HOORWITZ, Emanuel, Captain, Alcatraz Island, Calif., Fort McDowell,
Calif.
HUDSON, Charles B., 1st Lieut., Oakland, Calif., Presidio of Monterey,
Calif.
KELTZ, Charles, 1st Lieut., Los Angeles, Presidio of Monterey, Calif.
MASON, James L., Captain, Los Angeles, Presidio of Monterey, Calif.
MITCHELL, Charles S., 1st Lieut., Fresno, Calif., Presidio of Monterey,
Calif.
NAGEL, Sherman A., Jr., 1st Lieut., Los Angeles, Presidio of Monterey,
Calif.
NEUGARTEN, Kurt, 1st Lieut., San Francisco, Presidio of Monterey,
Calif.
PALMER, Alfred M., 1st Lieut., San Francisco, Fort Lewis, Wash.
SCHENK, Harry Leon, 1st Lieut., Los Angeles, Presidio of Monterey,
Calif.
SLAUGHTER, Howard C., Major, Los Angeles, Presidio of Monterey,
Calif.
SPEAKER, Otho F., 1st Lieut., Glendale, Calif., Fort MacArthur, Calif.

Orders Revoked
STRANQUSIT, Henry C., Major, Ogden, Utah.

ORGANIZATION SECTION

OFFICIAL NOTES

THE CLEVELAND SESSION

Section Representatives to Scientific Exhibit

Representatives to the Scientific Exhibit have been appointed from the different sections of the Scientific Assembly as follows:

- Practice of Medicine—Louis B. LaPlace, 1900 Rittenhouse Square, Philadelphia.
Surgery, General and Abdominal—Grover C. Penberthy, 1553 Woodward Avenue, Detroit.
Obstetrics and Gynecology—H. Close Hesseltine, 5841 Maryland Avenue, Chicago.
Ophthalmology—Georgiana Dvorak Theobald, 120 Medical Arts Building, Oak Park, Ill.
Laryngology, Otology and Rhinology—Fred W. Dixon, 2060 East Ninth Street, Cleveland.
Pediatrics—Arthur F. Abt, 104 South Michigan Avenue, Chicago.
Pharmacology and Therapeutics—O. P. J. Falk, 539 North Grand Boulevard, St. Louis.
Pathology and Physiology—F. W. Konzelmann, Temple University Hospital, Philadelphia.
Nervous and Mental Diseases—F. P. Moersch, 102 Second Avenue, S.W., Rochester, Minn.
Dermatology and Syphilology—Hamilton Montgomery, 102 Second Avenue, S.W., Rochester, Minn.
Preventive and Industrial Medicine and Public Health—Paul A. Davis, 1436 Delia Avenue, Akron, Ohio.
Urology—John H. Morrissey, 40 East Sixty-First Street, New York.
Orthopedic Surgery—Theodore A. Willis, 10515 Carnegie Avenue, Cleveland.
Gastro-Enterology and Proctology—Sara M. Jordan, 605 Commonwealth Avenue, Boston.
Radiology—S. W. Donaldson, 326 North Ingalls Street, Ann Arbor, Mich.
Anesthesiology—Paul M. Wood, 745 Fifth Avenue, New York.

Application blanks for space in the Scientific Exhibit at the Cleveland session may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

American Medical Golfing Association

In 1913 Dr. Will Walter first suggested the founding of a medical golfing association to Dr. Wendell Phillips, then a trustee of the American Medical Association, who responded with an enthusiasm which continued until his death in 1934. The organization work, which fell to Dr. Walter, was completed in time for the initial tournament, which was held at the San Francisco Country Club in 1915. A tournament has been held by the golfing association during the time of the annual session of the American Medical Association each year since 1915. Following is a list of the tournaments, where they were held, the champion, and the president and vice president:

The average attendance of players at the tournaments has been about 210. Their popularity has increased until it has become necessary to select a country club which has two eighteen hole courses or to take over two courses which are adjacent to each other, as was done in Kansas City in 1936 and as will be done in Cleveland in 1941. The present membership of the golfing association is 1,610 fellows in all parts of the United States, Hawaii, Cuba and the Philippine Islands.

The 1941 tournament of the American Medical Golfing Association will be held at the Cleveland Country Club and Pepper Pike in Cleveland during the annual meeting of the American Medical Association in that city, June 2-6. This year's president of the American Medical Golfing Association, Dr. E. H. Houston of Seattle, has had a long golfing career. He has been president and captain of the largest municipal links in Seattle and a member of its board of trustees for fifteen years, and president of the golfing section of the Washington State Medical Association for the last sixteen years. He was chairman of the greens committee of one club for twenty-five consecutive years. The physicians of British Columbia and King County Medical Society, Washington, for twenty-two years have had an annual golfing tournament, and Dr. Houston has been president of the King County group. He has regularly attended the tournaments of the American Medical Golfing Association for years and already he has completed all arrangements for the next tournament of the American Medical Golfing Association.

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the American Medical Association meeting at Cleveland on June 3, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the programs at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and

Tournament	Year	Club	Champion	President	Vice President
First	1915	San Francisco Country Club	James Eaves	Wendell Phillips*	Will Walter
Second	1916	Detroit Country Club	Fred Bailey	Wendell Phillips*	Will Walter
Third	1917	Garden City Golf Club, New York	A. F. Henning	Thomas Hubbard	Will Walter
Fourth	1918	Glenview Club, Chicago	F. M. Caster	Fred Bailey	Will Walter
Fifth	1919	Atlantic City Country Club	Fred	Martin	Will Walter
Sixth	1920	New Orleans Country Club	A. F.	Marvel*	Will Walter
Seventh	1921	Common Country Club, Boston	Charlt	Moss	Will Walter
Eighth	1922	Glen Echo Club, St. Louis	Fred Bailey	Charlton Wallace	Will Walter
Ninth	1923	San Francisco Country Club	E. Seaforth	Will Walter	Fred Bailey
Tenth	1924	Olympia Fields, Chicago	George McKee	James Eaves	Fred Bailey
Eleventh	1925	Seaview, Atlantic City	Homer Nicoll	D. Chester Brown	Lorenzo Walter
Twelfth	1926	Dallas Country Club	S. M. Hill	Henry Cotton*	Walt Conaway
Thirteenth	1927	Columbia Country Club, Washington	George McKee	Samuel Childs	Leland Ellis
Fourteenth	1928	Minneapolis Country Club	Walter Sheldon	W. D. Shelden	H. H. Kerr
Fifteenth	1929	Waverly Country Club, Portland	John Loudon	Ben Thomas*	G. J. Thomas
Sixteenth	1930	Hawthorne Country Club, Detroit	John Loudon	Walter Schaller	J. L. McCool

Twenty-fourth	1938	San Francisco Golf and Country Club	J. A. Marek	Walt P. Conaway	George W. Hall
Twenty-fifth	1939	Norwood Hills Country Club, St. Louis	Duke R. Gaskins	E. S. Edgerton	James W. Morgan
Twenty-sixth	1940	Winged Foot Golf Club, Mamaronek, New York	John M. Murphy	George W. Hall	Grayson Carrell

*Deceased

broadcast it at another hour or even on another day. It is advisable therefore to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles

will be announced weekly in THE JOURNAL and monthly in *Hygeia*, the Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

- December 4. Paging Dr. Drew.
- December 11. The Family's First Friend.
- December 18. A Stitch in Time.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. Res. 630 has passed the House, providing that an additional assistant in the attending physician's office of the House of Representatives shall be paid the sum of \$30 a month from the contingent fund of the House until otherwise provided for by law. H. R. 10278 has passed the House and Senate, providing that until May 15, 1945, the Secretary of War may, in his discretion, dispense with any part of the examination for promotion in the Regular Army of officers of the Medical, Dental and Veterinary Corps, except those relating to physical examination. During the course of the consideration of this bill on the floor of the House, Repre-

sentative Crawford, of Michigan, proposed that original appointments in the Medical Corps of the Army "shall be made from among graduates of reputable schools or colleges of medicine or osteopathy, under such regulations as the Secretary of War shall prescribe." The amendment was not adopted.

DISTRICT OF COLUMBIA

Changes in Status.—H. R. 8665 has been reported to the Senate, providing for the issuance of a license to practice chiropractic in the District of Columbia to Lou Davis. H. R. 10418 has been reported to the Senate, authorizing the Commission on Licensure to issue a license to practice the healing art in the District of Columbia to Dr. Peter Florey.

WOMAN'S AUXILIARY

Georgia

The Mrs. James N. Brawner cup was won last year by the Woman's Auxiliary to the Ware County Medical Society at Waycross and the previous year by the auxiliary to the Baldwin County Medical Society at Milledgeville. Mrs. Brawner, of Atlanta, first president of the Woman's Auxiliary to the Medical Association of Georgia, presented the cup to the auxiliary for award at each annual meeting, the winner to retain possession until the following meeting. Mrs. Eustace A. Allen, of Atlanta, is chairman of the trophy committee and has compiled the list of credits that will govern the award of the cup this year. A yearbook will be stressed, health education programs, subscriptions to *Hygeia*, the payment of dues on time and an exhibit at the state meeting.

An auxiliary to the Gwinnett County Medical Society was organized at a meeting in Lawrenceville. Mrs. C. W. Roberts, of Atlanta, former president of the Woman's Auxiliary to the Medical Association of Georgia, was the chairman of organization. Mrs. D. C. Kelley, of Lawrenceville, was named president of the new group.

The Woman's Auxiliary to the Randolph County Medical Society met recently with Mrs. J. C. Patterson in Cuthbert.

Illinois

The Aux Plaines branch of the Cook County auxiliary met, September 27, in Oak Park with the president, Mrs. C. W. Stuart, presiding. One hundred and two members and guests were present. Among the honored guests were Mrs. H. J. Dooley, state president; Mrs. W. C. Bornemeier, county president; Mrs. R. K. Packard, past national president, and Mrs. W. J. Wanninger, national *hygeia* chairman.

The north side branch of the Cook County auxiliary met, September 16, at the McCormick Y. W. C. A., Chicago, with twenty-one members and three guest speakers present. The program was "Information Please." Mrs. R. K. Packard spoke on "Why an Auxiliary?" Mrs. C. G. Goodwin, parliamentarian of the Illinois Federation of Women's Clubs, on parliamentary procedure, and Dr. W. O. Thompson, secretary to the north side branch of the Chicago Medical Society, gave a short address and answered questions.

The Central Branch of the Woman's Auxiliary to the Cook County Medical Society met, October 2, at the Medical-Dental Arts Building, Chicago, with fifty members and guests present. Mrs. W. C. Bornemeier introduced the two guest speakers, Dr. Frank Maple, president of the Chicago Medical Society, and Mrs. H. J. Dooley, president of the state auxiliary. Both spoke on "The Aims and Objectives of the Auxiliary."

The St. Clair County auxiliary met, October 3, in the auditorium of St. Mary's Hospital, East St. Louis, with twenty-eight members present. The president, Mrs. O. M. McCann, presided. The speakers were Mrs. Ethelynn Sullivan, executive secretary of the St. Clair County Tuberculosis Association, and Dr. C. Milton Eberhart, district health superintendent of district number 16. Mrs. W. A. Griffith gave a report on legislative news and Mrs. I. L. Foulon reviewed *Hygeia*. Mrs. R. B. Ellis, radio chairman, presented "The Care of the Skin" on Station WTMU, October 7.

Wisconsin

The twelfth annual meeting of the state auxiliary was held in Milwaukee, September 17-19, with 354 members registered.

Mrs. V. E. Holcombe, president of the Woman's Auxiliary to the American Medical Association, was guest of honor. Three other national board members were present: Mrs. Robert Fitzgerald, chairman of revisions; Mrs. Eben J. Carey, a director, and Mrs. George H. Ewell, chairman of press and publicity.

The honorable Carl F. Zeidler, mayor of the city of Milwaukee, a guest speaker, commended the woman's auxiliary for its work in the field of improvement of public health and described the organization as a front line of defense for the ideals of American medicine. He predicted that in the coming legislative session many measures not in the interest of the health of Wisconsin citizenry would again be introduced, and he encouraged the studying of legislative bills and the dissemination of authentic information on them.

Mrs. Frank W. Pope is the retiring president, Mrs. Donne F. Gosin the president for 1940-1941 and Mrs. J. S. Supernaw the president-elect.

At the annual dinner Dr. Eben J. Carey, dean of Marquette University School of Medicine, gave an address.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 1931.

CALIFORNIA

The Clinical Aspects of Dermatology.—The University of California Medical School, San Francisco, has announced plans for a refresher course on "Clinical Aspects of Dermatology," to be given in the University of California Hospital, January 6-8. The program will cover various common cutaneous conditions, including tumors. Surgical aspects of dermatology will be considered and there will be lectures on infectious diseases. Additional information may be obtained from the Dean's Office, University of California Medical School, Medical Center, San Francisco.

Society News.—The San Francisco County Medical Society devoted its meeting, October 8, to a symposium on "Can We Get Adequate Nursing Care?" The speakers were Dr. Russell V. Lee, Palo Alto, from the point of view of the general practitioner; Dr. Anthony J. J. Rourke, the hospital superintendent; Marjorie Hart, R.N., private duty nurse; Sally Heitman, R.N., nurses' training school, and Helen Reynolds, R.N., visiting nurse.—Mr. Arthur Cornelius Jr., director of the Los Angeles office of the Federal Bureau of Investigation, discussed "Present Day Problems of Law Enforcement, with Special Reference to Cooperation from the Medical Profession" before the Hollywood Academy of Medicine, October 10.

IDAHO

Life Membership in State Society.—Dr. Joseph N. Davis, Twin Falls, was presented with life membership in the Idaho State Medical Association, September 12, as a token of appreciation for many years of faithful and efficient service. Dr. Davis has attended every annual session of the state association since becoming a member in 1913. He served as secretary-treasurer from 1922 until 1931, when he was made president-elect. From 1935 to 1938 he was a councilor. He was elected secretary-treasurer again in 1938, serving until this year, when he asked to be relieved. He is now state chairman for the Committee on Medical Preparedness of the American Medical Association.

EDITORIAL NOTE.—As we go to press, news is received that Dr. Davis was killed in an automobile accident, November 6.

ILLINOIS

Postgraduate Conference.—The Madison County Medical Society will be host at a postgraduate conference arranged by the state medical society for physicians in the sixth district in Alton, December 4. The following program will be presented by Chicago physicians:

- Dr. Henry Close Hesselstine, Newer Endocrines in Obstetrics.
- Dr. Lowell D. Snorf, Diagnosis and Treatment of Functional Disorders of the Colon.
- Dr. Clifford J. Barborka, Medical Management of Gallbladder Disease.
- Dr. Wilber E. Post, Arthritis.
- Dr. Hillier L. Baker, Potential Inguinal Hernia with Special Reference to Direct Hernia.
- Dr. Archibald L. Hoyne, Scarlet Fever.
- Dr. Arno B. Luckhardt, Academic or Unsuccessful Research.
- Dr. Warren H. Cole, Hypertthyroidism.

Chicago

Public Lecture by Dr. Ebaugh.—Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado School of Medicine, Denver, will address a public meeting sponsored by the Chicago Medical Society in cooperation with the Chicago Pediatric and Neurological societies, December 11, at the Chicago Woman's Club. His subject will be "Your Mental Health."

Branch Meetings.—Dr. John de J. Pemberton, Rochester, Minn., discussed "Indications for Splenectomy and the Results of Operation" before the North Side Branch of the Chicago Medical Society, November 7. Dr. Albert M. Snell, Rochester, addressed the Evanston Branch, November 7, on "Recent Studies on Deficiency States and Vitamin Therapy" and Dr. Charles B. Puestow, "Relation of Vitamins to Surgery."

Society News.—The Chicago Council of Medical Women was addressed, November 13, by Drs. Mila I. Pierce, Evanston, on "Infections of the Newborn"; Louise O. Kappes, Evanston, "Allergy in Children," and Willie Mae Clifton, "Dietary Treatment of Phosphorus Retention in Renal Insufficiency."—The Chicago Gynecological Society was addressed, November 15, among others, by Drs. Milton H. Adelman and Benjamin B. Lennon on "Pituitrin Shock."

IOWA

District Meeting.—The Iowa and Central Illinois District Medical Association held its winter meeting in Davenport, November 15. Dr. Rieber C. Hovde, Davenport, gave a "Statistical Analysis of 115 Consecutive Operations on the Biliary Tract" and Dr. Donald Guthrie, Sayre, Pa., "Diagnosis of Diseases of the Thyroid Gland and Their Treatment."

Annual Fracture Clinic.—The fourth annual "fracture day" sponsored by the fracture committee of the Iowa State Medical Society was held in Cedar Rapids, November 14, in conjunction with the meeting of the Linn County Medical Society. The session was devoted to a symposium on fractures of the spine with the following speakers: Drs. George L. Apfelbach, Chicago; Arthur Steindler, Frank R. Peterson and Clarence E. Van Epps, Iowa City; Arthur W. Erskine and Robert M. Wray, both of Cedar Rapids; Douglas N. Gibson, Lewis M. Overton and Francis A. Ely, Des Moines. The clinic was concluded with a lecture by Dr. Donald Guthrie, Sayre, Pa., on "Thyroid Disease." Dr. Guthrie was the guest speaker of the Linn County Medical Society.

MARYLAND

The Noguchi Lectures.—Dr. Heinrich Zimmer, formerly professor of Sanskrit at the University of Heidelberg, delivered the Hideyo Noguchi Lectures at the Institute of the History of Medicine, Johns Hopkins University School of Medicine, Baltimore. The general subject was "Hindu Medicine," presented in three parts:

- November 25, Medical Tradition and the Human Body.
- November 27, The Physician and His Concept of Dietetics.
- November 29, Diseases and Cures.

Professor Pearl Dies.—Raymond Pearl, Ph.D., professor of biology, Johns Hopkins University School of Medicine, Baltimore, died suddenly in Hershey, Pa., November 17, of coronary thrombosis, aged 61. Born in Farmington, N. H., June 3, 1879, Dr. Pearl graduated at Dartmouth College in 1899, where he also received an honorary degree in science in 1919. He received his degree in philosophy from the University of Michigan in 1902, an honorary doctorate in laws from the University of Maine in 1919 and one in letters from St. John's College, Annapolis, in 1935. Dr. Pearl began his career as assistant zoologist at Michigan in 1899, becoming instructor in 1902. In 1906 he went to the University of Pennsylvania for one year. From 1907 to 1918 he was biologist and head of the department of biology at the Experimental Station in Maine. He became professor of biometry and vital statistics at the Johns Hopkins University School of Hygiene and Public Health in 1918, serving as research professor from 1925 to 1930. He was named professor of biology in the school of medicine in 1923 and in the school of hygiene and public health in 1930, holding both positions until his death. He was director of the institute of biologic research at the school from 1925 to 1930. He was president of the International Union for Scientific Investigation of Population Problems from 1928 to 1931 and later of other scientific bodies. He wrote extensively on his subject.

MASSACHUSETTS

Society News.—Dr. Richard H. Overholt, Brookline, addressed the Trudeau Society of Boston, October 24, on "The Management of Pulmonary Abscess."—The Northeastern Conference on Mental Health was to be held in Salem, November 15; the speakers included Drs. Ira S. Wile, New York, "Mental Health of the Community," and Harry C. Solomon, Boston, "Diagnosis and Treatment of Mental Disorders."

Memorial Meeting to Dr. Maude Abbott.—The New England Heart Association held a special meeting at the Boston Medical Library, November 8, in honor of the late Dr. Maude E. S. Abbott, formerly assistant professor of medical research and curator of the medical museum, McGill University Faculty of Medicine, Montreal. The speakers were:

- Dr. Charles F. Martin, Montreal, Dr. Abbott and McGill University.
- Dr. Paul D. White, Boston, Her Contribution to Cardiology.
- Dr. Emanuel Libman, New York, Personal Reminiscences.
- Dr. Helen B. Taussig, Baltimore, Changes Which Occur During Life in Patients with Congenital Malformations of the Heart.

MINNESOTA

Personal.—Dr. Bertram S. Adams, Hibbing, president of the Minnesota State Medical Association, was honored at a dinner, October 22. Dr. Adams had been selected as the "seventh annual honor night choice" by the Hibbing Elks Lodge. —Dr. William F. Braasch, Rochester, was recently made a corresponding member of the Sociedad Venezolana de Urología and of the Sociedad Cubana de Urología.

Society News.—Dr. Walter Henry Valentine, Tracy, has been named president of the Southern Minnesota Medical Association and Dr. Nelson W. Barker, Rochester, reelected secretary-treasurer. —Dr. Julian F. DuBois, Sauk Centre, has been chosen president of the Northern Minnesota Medical Association and Dr. Clarence Jacobson, Chisholm, secretary. —Dr. William F. Braasch, Rochester, addressed the Minnesota Academy of Medicine, November 13, in St. Paul, on "Hypertension and Surgical Disease of the Kidney." Dr. William A. H. Hanson, Minneapolis, presented his thesis on "Tumors Simulating Carcinoma—Hand-Schüller-Christian's Disease."

NEW YORK

Society News.—Drs. Wardner D. Ayer and Abraham C. Silverman addressed the Onondaga County Medical Society, Syracuse, November 4, on "Chronic Cerebral Disease—A Critical Review with Special Reference to Diagnosis and Treatment" and "Outbreak of Poliomyelitis in a Child-Caring Institution in Syracuse" respectively. —At a meeting of the Syracuse Academy of Medicine, November 19, the speakers were Drs. Marguerite P. McCarthy, Solvay, and Joseph R. Wiseman on "An Analysis of Treated Hay Fever Patients at the Allergy Clinic, Syracuse Free Dispensary"; Frederick S. Wetherell, "Nodular (Adenomatous) Goiter—Present Day Concepts of Its Management," and Robert C. Schwartz, "Patent Ductus Arteriosus, with Operation—Case Report."

New York City

The Welch Lectures.—Dr. Francis Peyton Rous, member of the Rockefeller Institute for Medical Research, will deliver the William Henry Welch Lectures, presented by Mount Sinai Hospital, December 6 and 9. Dr. Rous's subjects will be "Conditions Determining Cancer" and "The Known Causes of Cancer."

Meeting on Chronic Pulmonary Diseases.—The Tuberculosis Sanatorium Conference of New York will hold a clinical session on chronic pulmonary diseases at Cornell University Medical College, December 11. The program will be presented by the staff of the Municipal Sanatorium, Otisville, as follows: Drs. Samuel A. Thompson, New York, and Mortimer Greenberg, Otisville, "A Plea for the Early Jacobaeus Operation in the Treatment of Incomplete Collapse Therapy"; Joseph Emerson Noll, Port Jervis, "Data Concerning Location and Measurements of Pulmonary Cavities and Foreign Bodies," and Milton S. Lloyd, "Pulmonary Drainage: Its Relation to Collapse Therapy in the Treatment of Tuberculosis."

Friday Afternoon Lectures at the Academy.—Dr. Irving S. Wright delivered the fourth Friday Afternoon Lecture of the current series at the New York Academy of Medicine, November 29, on "Thrombophlebitis—Recent Advances in Knowledge and Treatment." Coming lectures will be:

Dr. Ralph H. Boots, Gold Therapy in Rheumatoid Arthritis, December 6.

Dr. James William Hinton, Cancer of the Stomach: Early Diagnosis and Surgical Indications Based on the Review of 700 Cases, December 13.

Dr. Norman H. Plummer, Specific Treatment of Pneumonia, January 3. Dr. Tracy J. Putnam, The Nature and Treatment of Epilepsy, January 10.

Dr. John Scudder, Newer Knowledge of Blood Transfusion, January 17. Dr. Kenneth R. McAlpin, Blood Diseases from the Standpoint of the Clinician, January 24.

Previous lectures in the series were: Drs. Harold J. Stewart on "Digitalis Therapy: Mechanism of Its Action in Congestive Heart Failure," November 1; Harold T. Hyman, "Massive Dose Chemotherapy or Intravenous Drip Chemotherapy," November 8, and Thomas Duckett Jones, Boston, "Care of the Patient with Rheumatic Fever," November 15.

NORTH CAROLINA

Special Society Meetings.—Dr. Milton R. Gibson, Raleigh, was elected president of the North Carolina Eye, Ear, Nose and Throat Society at its annual meeting in Winston-Salem, recently. Dr. Thomas C. Kerns, Durham, was made vice president and Dr. Vanderbilt F. Couch, Winston-Salem,

secretary. Guest speakers at the meeting were Drs. William Thornwall Davis, Washington, D. C., on "Physiotherapy in Ophthalmology" and "Medical Ophthalmology" and Edward A. Looper, Baltimore, on "Cancer of the Larynx" and "Laryngeal Tuberculosis." The society voted to require that henceforth applicants for membership must have passed examinations of the American Board of Ophthalmology or the American Board of Otolaryngology. —Dr. Robert W. McKay, Charlotte, was elected president of the North Carolina Urological Association at the annual meeting in Greensboro, October 14. Dr. John W. Frazier Jr., Salisbury, was elected vice president and Dr. William C. Lott, Asheville, secretary. The guest speaker at the meeting was Dr. Roy B. Henline, New York, who spoke on "Adequate Treatment of Prostatic Disease from a Pathological Viewpoint."

PENNSYLVANIA

Easton Hospital Fifty Years Old.—The fiftieth anniversary of the founding of Easton Hospital, Easton, was observed November 11. Open house was held at the hospital and a plaque honoring the first board of trustees was unveiled. The hospital was established in 1890 with a fund of \$7,000 raised by a hospital bazaar, said to have been the most important social event in the town's history. The first building, a remodeled residence, had ten beds. Additions were made in 1894 and a new brick building replaced the early frame structure in 1906. The present building, with facilities for 192 patients and twenty-one newborn infants, was built in 1930.

Philadelphia

The DeSchweinitz Lecture.—Dr. Frederick H. Verhoeff, Boston, delivered the third annual DeSchweinitz Lecture before the section of ophthalmology of the College of Physicians of Philadelphia, November 20. His subject was "Occlusion Hypertropia."

Anthrax and Industry.—The bureau of industrial hygiene of the Pennsylvania Department of Health and the Philadelphia Department of Health sponsored a symposium on anthrax, November 19, at the Philadelphia County Medical Society Building. The speakers were:

Col. Arthur Parker Hitchens, History and Biology of the Anthrax Bacillus.

Dr. Pascal F. Lucchesi, Treatment of Anthrax.

Dr. Henry Field Smyth, Anthrax in the United States.

Ivor Griffith, Ph.M., The Felt Hat Industry.

Harry D. Immel, Pennsylvania Department of Labor and Industry, The Enforcement Problem.

Dr. William B. Fulton, Joseph F. Meller Jr. and William H. Kreeker Jr., bureau of industrial hygiene, state health department, Harrisburg, An Anthrax in Philadelphia.

L. B. F. Raycroft, Industrial Hygiene Association, Helpful Relationships for Prevention of Anthrax.

Pittsburgh

Society News.—Speakers at a meeting of the Pittsburgh Academy of Medicine, November 12, were Drs. Bender Z. Cashman on "The Role of Deep Cauterization in the Prevention of Cancer of the Cervix"; Charles Russell Schaefer, Pittsburgh, "Glycolysis in Leukemia," and William A. Heazlett, Wilkinsburg, "Masked Diabetes Insipidus." —Drs. James H. Rankin Jr. and Michael Cammarata, Woodville, addressed the Pittsburgh Neuropsychiatric Society, November 18, on "Fracture Prevention in Metrazol Treatment; Demonstration of Technic" and "Treatment of Epilepsy, with Special Reference to Dilantin" respectively.

VIRGINIA

Portrait of Dr. Tucker.—Ex-residents of Tucker Sanatorium, Richmond, presented a portrait of Dr. Beverly R. Tucker to the sanatorium recently. Dr. Thomas G. Hardy, Farmville, made the presentation for the ex-residents and Dr. Howard R. Masters accepted for the sanatorium. Dr. James Asa Shield presided at the exercises, which were attended by a number of ex-residents now practicing in other cities.

Regional Meetings.—The Southwestern Virginia Medical Society met at the Southwestern State Hospital in Marion, October 2, with Drs. Russell L. Haden, Cleveland, and David C. Wilson, Charlottesville, as the guest speakers on "Treatment of Anemia" and "New Drugs in Neuropsychiatry" respectively. —The Clinch Valley Medical Society held a meeting at Norton, October 18, with the following speakers: Drs. James T. Tucker, Richmond, on "The Use of Modern Drugs in Traumatic and Orthopedic Surgery"; Henry C. Spalding, Richmond, "Practice of Obstetrics in the Home"; Fred J. Wampler, Richmond, "Progress in the Prevention of

Diseases"; George Fordham, Powellton, W. Va., "Developing a Medical Program for a Coal Industry," and Mr. R. T. Homewood of the state health department, who outlined the part that the bureau of industrial hygiene may play in a health program for the mining industry.

WASHINGTON

Society News.—The fall meeting of the Pacific Northwest Dermatological Society was held in Spokane, October 17. Dr. Hamilton Montgomery, Rochester, Minn., was the guest speaker on "Pathology of Skin Diseases."—Speakers before the King County Medical Society, Seattle, November 4, were Drs. Philipp Schonwald, on "Fungus Allergies"; James E. S. Stroh, "Treatment of the Acute Asthmatic Patient," and Alexander R. Altose, "The Allergic Nose." All are of Seattle.—Dr. Joseph A. Beeman, Portland, Ore., addressed the Spokane County Medical Society, Spokane, November 14, on "The Role of the Medical Profession in Criminal Investigation."

GENERAL

Conviction of Norman Baker Sustained.—On November 22 the conviction of Norman Baker and his two associates R. A. Bellows and Dr. J. L. Statler, on a charge of using the mails to defraud, was affirmed by the Eighth Circuit Court of Appeals at St. Louis. In January 1940 Baker was sentenced by the Federal District Court to four years in prison and fined \$4,000 in connection with the promotion of his cure for cancer.

Venereal Disease Rates in Cities and States.—The U. S. Public Health Service has issued a statement on the prevalence of syphilis and gonorrhea in cities for the fiscal year 1940; some of the rates for cities, however, are based on fewer than twelve months. A statement has also been issued giving the rates for these diseases by states. The total annual rate for syphilis per thousand of population was 3.68 and varied for the various states from 0.37 for Wisconsin to as much as 20.34 for Mississippi. The syphilis rate for the Virgin Islands was 20.09, Florida 13.94, District of Columbia 10.76 and South Carolina 10.27. The annual rate per thousand of population for gonorrhea totaled 1.36, varying from 0.40 for Wisconsin to 14.39 for Mississippi. The gonorrhea rate for the Virgin Islands was 9, District of Columbia 5.36, Alaska 3.92 and Arizona 3.28. The data on which these reports were based were monthly reports from state and city departments of health. The total number of new cases of syphilis reported by states for the month of August 1940 was 38,088, and of new cases of gonorrhea 15,921. The new syphilis cases reported included primary, secondary, early latent and congenital cases.

Academy of Dermatology and Syphilology.—The third annual meeting of the American Academy of Dermatology and Syphilology will be held at the Palmer House, Chicago, December 8-11. The preliminary program announces that there will be special courses, luncheon round table discussions, clinical presentations, lectures and symposiums. Courses in histopathology and mycology and the clinical presentations will be at the University of Illinois College of Medicine. Among subjects of the symposiums will be: physiology and chemistry of the skin, led by Dr. Donald M. Pillsbury, Philadelphia; pharmaceutical therapeutics, by Dr. Otto H. Foerster, Milwaukee; allergy, by Dr. Samuel M. Peck, New York, and syphilis, by Dr. Udo J. Wile, Ann Arbor, Mich. Addresses will be given by the following:

- Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Diseases of the Blood and Blood Forming Organs: Their Relation to the Skin and Mucous Membranes.
- Dr. Edward A. Oliver, Chicago, Rare Dermatoses.
- Dr. Lyle B. Kingery, Portland, Ore., Recent Advances in Our Knowledge of the Ringworm Infections.
- Dr. Elmer L. Sevringhaus, Madison, Wis., Endocrines and Their Relation to Dermatology.
- Dr. William F. Petersen, Chicago, The Patient, His Skin and the Weather.

Annual Meeting of Infantile Paralysis Foundation.—The National Foundation for Infantile Paralysis held its first annual medical meeting, November 7-8, at the Waldorf-Astoria Hotel, New York. Reports were heard from the committees on virus research, public health (epidemics), research for the prevention and treatment of after-effects, education, medical publications and nutritional research. The committees recommended grants totaling \$150,580 for the coming year, including one of \$6,600 for epidemic aid in the Philippine Islands. Dr. Herman N. Bundesen, Chicago, was elected chairman of the committee on public health (epidemics) to succeed Dr. Thomas Parran, surgeon general. U. S. Public Health Service, Wash-

ington, D. C., who resigned because of the pressure of other activities. Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, was elected chairman of the committee on medical publications to succeed Dr. Max M. Peet, Ann Arbor, Mich. The following chairmen were reelected: Drs. Thomas M. Rivers, New York, committee on virus research; Philip Lewin, Chicago, committee on research for prevention and treatment of after-effects; James S. McLester, Birmingham, Ala., committee on nutritional research, and Dr. Peet, committee on education. At a banquet Thursday evening Mr. Basil O'Connor, New York, president of the foundation, delivered the principal address. The dinner was attended by 120 persons, including committee members, trustees and officers, forty-four grantees of previous years and newspaper science editors and writers.

National Institute of Health Studies Problems of Aging.—A new unit formed in the National Institute of Health for the study of problems of aging, called the Unit on Gerontology, announces that it is conducting a survey of the present trends of active and contemplated investigations in this field. Inquiries about studies on aging are being sent to scientists in the basic biologic sciences as well as to clinical investigators, in the belief that much fundamental work on the processes, mechanisms and consequences of senescence is going on in sciences related to medicine. Critical analysis of the information elicited by such a survey may be expected to serve several purposes, the announcement said. It should facilitate closer cooperation among investigators interested in related problems and it will emphasize the urgent need for augmented support of studies for the problems of senescence. It will reveal "blank spots" in research that may justify special emphasis in the future and will be an invaluable aid in formulating future research programs, it was said. Dr. Edward J. Stieglitz, Garrett Park, Md., is in charge of the investigations in gerontology, and the following national advisory committee has been appointed:

- Dr. Lewis R. Thompson, director, National Institute of Health, Washington, D. C.
- Dr. Anton J. Carlson, Frank P. Hixon distinguished service professor emeritus of physiology, University of Chicago.
- Dr. Charles L. Christiernin, New York, medical director, Metropolitan Life Insurance Company.
- Robert E. Coker, Ph.D., professor of zoology, University of North Carolina, Chapel Hill, N. C.
- William Crocker, Ph.D., director, Boyce Thompson Institute of Plant Research, Yonkers, N. Y.
- Mr. Lawrence K. Frank, sociologist, Josiah Macy Jr. Foundation, New York.
- Albert Baird Hastings, Ph.D., Hamilton Kuhn professor of biological chemistry, Harvard University, Cambridge, Mass.
- Dr. Ludvig Hektoen, Chicago, consultant, National Cancer Institute, U. S. Public Health Service.
- Dr. Winfred Overholser, superintendent, St. Elizabeths Hospital, Washington, D. C.
- Dr. Clarence D. Selby, medical consultant, General Motors Corporation, Detroit.
- Dr. William D. Stroud, professor of cardiology, The Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, Philadelphia.

A conference of this committee was held at the institute, November 25-26. Information concerning subjects under investigation and the methods of approach is earnestly solicited. Letters should be addressed to Dr. Stieglitz, In Charge, Investigations in Gerontology, National Institute of Health, Bethesda, Md.

FOREIGN

Physicians in the New Germany.—According to the *Münchener medizinische Wochenschrift*, Germany now has (in the region of the old reich) 59,454 physicians, compared to 55,259 during 1937. During the latter year Germany still had 4,220 Jewish physicians. In the "Ostmark" (Austria) the estimated number of physicians is 7,000, in the Sudeten district 2,000. If the numerous approbations during last year are counted in, the total number of physicians may be estimated at approximately 75,000. Three Japanese women physicians have arrived in Berlin for a half-year's stay in Germany. In Japan two of them were active in gynecologic clinics and one in the department for infants in a Red Cross hospital. Their studies in women's occupations, social work and medicine will be made under the patronage of the "Reichsfrauenführung" (women's organization of the reich) and of the "Reichsärzteführer" (leader of the physicians of the reich). Japan has at present 5,500 women physicians. By a decree of the Rumanian minister of health, thirty-four Jewish physicians who were active as county physicians were dismissed; the dismissal was effective immediately. Likewise thirty-one Jewish physicians connected with the social insurance were removed from their positions.

LONDON

(From Our Regular Correspondent)

Nov. 2, 1940.

Medical Education Under the Air Raids

London has twelve medical schools, without counting post-graduate ones, the greatest number in any city in the world. The continuous bombing has damaged many of the hospitals to which they are attached as well as school buildings. But medical education is not interrupted, though it goes on in a different way. London was divided into sectors with the great hospitals at the apexes and connected to affiliated hospitals in the surrounding country, to which most of their patients were removed, so that they could be used as casualty clearing stations for the victims of air raids, who were expected to number many thousands. Thanks to our defenses and air raid precautions the number has been much smaller. The students were dispersed to the "sector hospitals." It was hoped to resume normal teaching at the London hospitals on the opening of this winter session. But the bombing, which has seriously damaged some of them, has prevented this. St. Thomas's Hospital received three direct hits from bombs in six days and had to be evacuated. Though the foundation of the hospital goes back to medieval times, the present building, with its eight linked pavilions and medical school on the bank of the Thames, is one of the most modern of the London hospitals. It has been necessary to make arrangements for the preclinical teaching in the country as well as for the clinical teaching at sector hospitals. The London hospital has been hit several times but the walls have not been damaged and there have been no casualties. However, the precaution has been taken of reducing the number of beds, and now only acutely ill patients and casualties are admitted. But systematic teaching continues at the hospital, though clinical work is done by the students at the sector hospitals in the mornings. They return in the afternoons to the hospital for the systematic teaching. One new advantage is that, while in peace time only 800 beds were available at the London Hospital, the sector hospitals provide 10,000. Similar arrangements are made by the other schools. The preclinical students are sent to medical schools in other cities, some as distant as Bristol and Cardiff, or to improvised schools in the country. While the material for the clinical students is much diminished at their own hospitals, they have the advantage of a much greater number of beds at the sector hospitals. Hence the remark of one dean that their education, though less academic, is more practical. The preclinical students of St. Bartholomew's Hospital are housed in the University Laboratories [censor]. Those of Guy's Hospital are receiving their tuition at temporary premises in [censor], those of University College Hospital at the [censor] National School [censor].

The Growing of Medicinal Plants

Few medicinal plants are grown in this country; we have to rely on imports, which the war has interrupted. The Ministry of Health, in collaboration with the Ministry of Agriculture, is taking measures to secure an adequate home supply of the four important plants belladonna, hyoscyamus, stramonium and digitalis. At the same time work is being done along genetic and ecologic lines to increase the yield of active principles from these plants. The Therapeutic Requirements Committee of the Medical Research Council has also recommended the production or collection of numbers of medicinal plants in Britain, such as colchicum, filix mas, hamamelis, pyrethrum. Bulletins on the growing of these plants are issued by the Ministry of Agriculture. More has not been done in this direction in the past because the plants could be imported at prices which would not

pay for their growing at home. It is also suggested by the Therapeutic Requirements Committee that more drugs should be grown in the British Empire, which can produce every important drug. Among the examples given are camphor, cascara sagrada, cinchona, coca, ipecacuanha, turpentine, santolin, thymol. It has been stated by J. C. Ghosh in his book "Indigenous Drugs of India" that half the drugs of vegetable origin in the British pharmacopeia are indigenous to India and that nearly all the others could be grown there.

The War Strain on Health Services

In Parliament the minister of health, Mr. Malcolm MacDonald, stated that the war had thrown a strain on our health services which they had successfully withstood. Because of the dangers of air raids, 730,000 children and 420,000 mothers were evacuated from industrial cities to the country. This huge migration was from populous areas where the necessary medical services were well established to areas where they were sparse. The difficult problem presented to the health authorities had to be met by swift improvisation. A skilled staff was recruited, and houses and other buildings were transformed into sick bays, residential nurseries, residencies for cripples and maternity homes. For London mothers alone homes were furnished in the country to cope with 2,800 confinements every month, and 500 expectant mothers were now leaving London every week. The evacuation of that much bombed city and of other cities was not a prelude to defeat nor the death agony of Britain but rather the unpleasant, the terrible but hopeful birth pangs of a new Britain. A fact about the new Britain was that the sojourn of London and other city children in the country had made them taller, heavier and more resistant to illness.

THE EMERGENCY HOSPITAL SERVICE

The Emergency Hospital Service was a remarkable creation. To the great resources of our hospitals had been added other public institutions, which by provision of operating rooms and equipment were transformed into first class hospitals. The permanent hospitals had been surrounded by new pavilions which could hold tens of thousands of extra patients. The number of air raid casualties was small compared with the efforts of the German airmen. At the moment only 5,500 beds had air raid casualties. Among the problems aggravated by the war was venereal disease. Its incidence had shown a large and steady decline in the past twenty years, but in the last few months there were indications of an increase. Local authorities were being asked to expand the existing services where necessary.

Precautions Against Disease in Air Raid Shelters

In a broadcast, Mr. Malcolm MacDonald, minister of health, spoke of the dangers to national health from overcrowding of air raid shelters in the coming winter and the arrangements to combat possible epidemics which might result. The most potent threat might be not the bomb and the parachute but the germs of influenza and other infectious diseases which generally can be held in check in peace time. The toughest new problem had been created by the gathering of people to sleep night after night in the large air raid shelters. Infectious diseases might lodge there and spread. The danger would be much reduced if the nightly population of the shelters was kept within reasonable proportions. Apart from influenza the dangerous disease most likely to spread to the camps and shelters this winter was cerebrospinal fever. But sulfapyridine had reduced the mortality of that disease to a fraction of what it was. Among the precautions to be taken was the setting up of medical aid posts in the large centers. There would be a nurse in regular attendance and a physician either in residence or on call. The shelters would be equipped to minister not only in cases of accident but for minor ailments which might be aggravated by the life in them.

In connection with the government's scheme to supply medicine for minor ailments in public shelters, it is proposed to set up local pharmacists' rotas for personal service. The War Emergency Council of the Pharmaceutical Society is discussing this development with the Ministry of Health. The stocks at these miniature underground pharmacies would be limited to a small range of preparations for immediate use by persons showing symptoms of nasal catarrh, throat and lung troubles or other ailments of an infectious nature. There would be an adequate supply of gauze pads to apply to the nose and mouth of persons with symptoms suggesting the presence of germs. These pads would be a signal to others to keep at a distance. Antiseptic compounds and surgical dressings would also be kept in readiness.

In the eighty stations of the London underground railways, 100,000 persons find shelter from bombs. They sleep on the platforms and passages in perfect safety. The latest arrangement is to distribute to them, by a special train, tea, coffee and cocoa, supplied at a charge of 2 cents per cup, and light refreshments, such as buns, biscuits, apples and sausage rolls, for which the maximum charge is 4 cents. The London County Council is providing 7,000 hot meals daily at its community centers for persons whose dwellings have been destroyed by bombs.

Criticism of the War Loaf

Nutritional experts have been stressing the superiority of bread made with wholemeal flour over that made with white flour because the latter is deficient in important ingredients, particularly vitamin B₁ and minerals. In spite of this, white bread remains much more popular than wholemeal. The government, which now controls and rations our food supply, has decided to fortify white bread by the addition of vitamin B₁ and calcium. This step was taken after receiving the report of a scientific committee. The decision has given rise to much controversy in the *Lancet*. In announcing this war bread in the House of Commons the minister of food described the drawbacks of wholemeal bread as unpalatability, indigestibility, lack of keeping qualities of white flour and invincible preference of the community for white bread. Sir Ernest Graham-Little, dermatologist and member of Parliament, points out that the report of a committee of the Royal Society on the digestibility of bread furnishes a direct negative to these allegations. Why did not the Ministry of Food follow the measures adopted in the last war on the advice of the committee of the Royal Society, one of which was the supply of a wholemeal war loaf? The measure now adopted involves the extraction from wheat of the major part of its vitamin content and the restoration of only vitamin B₁ in synthetic form. Graham-Little claims that the natural vitamin is superior to the synthetic. He also suggests that commercial interests are opposed to the loss of their trade in the by-products of the milling of white flour. A biochemist, R. A. Peters, contradicts Graham-Little as to the superiority of the natural vitamin and states that the synthetic vitamin is shown by every test—chemical, physical, biologic and clinical—to be equivalent. A cardiologist, Isaac Harris, is concerned about the addition of calcium to the bread. In his book "High Blood Pressure" he has shown that the kidney is exposed to a considerable strain when called on to excrete an excess of calcium and that a moderate administration has a profound influence on the character of the electrocardiogram.

The American Hospital Unit

The arrival of the American hospital unit, led by Dr. Philip Wilson, professor of orthopedic surgery at Columbia University College of Physicians and Surgeons, has been reported in previous letters. After landing at Liverpool the unit spent a week in visiting hospitals in the northwest under the guidance of Prof. Harry Platt of Manchester. It then came to London, where it was welcomed by the Ministry of Health and other

official bodies. After a survey, it was decided that it should take over a section of the war hospital at Park Prewitt, which in normal times is a mental hospital of 1,450 beds. General surgery is done there, but no orthopedic center existed and it is proposed that the American unit shall develop this. At the same time employment will be found in the department established in the hospital by Sir Harold Gillies for the member of the unit specializing in facial and maxillary surgery. But the idea of a separate American hospital has not been dropped. If the war becomes more intense and casualties increase, the unit reinforced from the United States will proceed to this work. Professor Wilson has cabled to America with a view to forming a neurosurgical team, which is desired by the British Emergency Medical Service. It would be accompanied by its own x-ray and laboratory technicians. In addition to clinical work Professor Wilson desires to carry out some research and he has been in touch with the British Medical Research Council so as to link up with it anything he may do in this direction.

A Physician Who Became an Anthropologist

The death at the age of 67 of C. G. Seligman, F.R.C.P., F.R.S., emeritus professor of ethnology in the University of London, has removed a man who began a distinguished career in the medical profession and abandoned it to become an eminent anthropologist. Seligman received his medical education at St. Thomas's Hospital, where he had a research scholarship under the pathologist S. G. Shattock. He was invited to join the Cambridge Anthropological Expedition, led by A. C. Haddon to the Torres Straits and Borneo. With Rivers, McDougall and Myers he began anthropological work on a tribe in North Queensland. He studied native diseases and collected information on native magic and customs. Returning to England he was appointed director of the clinical laboratory at St. Thomas's Hospital. But the attraction of anthropology proved too great and he embarked on an expedition which resulted in a monumental work, "The Melanesians of New Guinea." Returning to England again he worked at pathology for the last time, contributing to the Proceedings of the Royal Society a paper entitled "Observations on the Acquirement of Secondary Sexual Characters Indicating the Formation of an Internal Secretion of the Testicle." In 1908 he was commissioned by the government of India to work on the Veddas, a primitive people of Ceylon. The book that resulted was produced in collaboration with his wife and remains a standard work on the history and culture of these people. They also studied African ethnology and produced "The Pagan Tribes of the Nilotic Sudan," which was the first complete cultural survey of these people. In 1910 he was appointed lecturer on ethnology in the University of London and in 1913 professor. He applied psychoanalysis to the folklore and dreams of primitive people and endeavored to trace freudian phases in their sexual life.

Marriages

WILLIAM C. KEETTEL JR. to Miss Mary Helen Shinn, both of Iowa City, at Waverly, June 30.

RAYMOND A. NEWTON, Genoa, Neb., to Mrs. Helen Carstens of Chicago in Omaha, June 29.

KENNETH L. McSHANE to Miss Della Jacobson, both of Loveland, Colo., June 28.

CLARENCE F. BANTIN to Miss Angeline Phillips, both of Omaha, July 14.

GORDON MARTIN to Miss Neva Cocklin, both of Lincoln, Neb., June 14.

LOUIS R. NASH to Mrs. Madeline Carey, both of Ingleside, Neb., July 6.

Deaths

Charles Edward Humiston ☉ Chicago; College of Physicians and Surgeons of Chicago, 1896; an Affiliate Fellow of the American Medical Association; member of the House of Delegates of the American Medical Association, 1915, 1916, 1918, 1919 and from 1921 to the special session of 1935; a member of the Council on Medical Education and Hospitals of the American Medical Association from 1930 to 1937; past president of the Illinois State Medical Society; past president and secretary of the Chicago Medical Society; professor of surgery emeritus at his alma mater, now known as the University of Illinois College of Medicine; formerly on the staffs of the Chicago State Hospital and the Cook County Hospital; in 1922 was awarded the honorary degree of doctor of science from Marietta (Ohio) College; aged 72; co-founder, president of the West Suburban Hospital Association, from 1911 to 1914; member of the board of directors and trustee and for many years on the staff of the West Suburban Hospital, Oak Park, where he died, November 4, of encephalomalacia, cerebral thrombosis and arteriosclerosis.

Quitman Underwood Newell ☉ St. Louis; University of Alabama School of Medicine, 1911; assistant, instructor, assistant professor, associate professor from 1915 to 1935 and professor of clinical obstetrics and gynecology at the Washington University School of Medicine; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Southern Surgical Association and the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; president-elect of the Southern Medical Association; served during the World War; associate obstetrician and gynecologist, Barnes, St. Louis Maternity and St. Louis Children's hospitals; obstetrician and gynecologist, St. Luke's and Missouri Baptist hospitals; aged 54; died, November 4, of coronary sclerosis.

Arthur Carroll Scott ☉ Temple, Texas; Bellevue Hospital Medical College, New York, 1886; member of the House of Delegates of the American Medical Association, 1911, 1924, 1925, 1926, 1927; member and past president of the Southern Surgical Association; past president of the State Medical Association of Texas, Central Texas Medical Society and the Texas Association of Railway Surgeons; fellow and member of the board of governors of the American College of Surgeons; formerly member of the state prison board; chief surgeon, Gulf, Colorado and Santa Fe Hospital; founder and president on the staff of the Scott and White Hospital; aged 75; died, October 27, of coronary occlusion.

Pascal Brooke Bland ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1901; assistant professor of gynecology at his alma mater from 1915 to 1925 and professor of obstetrics from 1925 to 1937, when he was made professor emeritus; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; fellow of the American College of Surgeons; past president of the Obstetrical Society of Philadelphia; consulting obstetrician to the Jefferson Hospital; author of "Gynecology, Medical and Surgical" and "Obstetrics for Students and Practitioners"; aged 65; died, October 31, in the Bryn Mawr (Pa.) Hospital of a self-inflicted bullet wound.

William Henry Holmes ☉ Chicago; Northwestern University Medical School, Chicago, 1910; professor of medicine at his alma mater; member of the Central Society for Clinical Research; served during the World War; on the staffs of the Wesley Memorial Hospital and the Passavant Memorial Hospital; author of a book entitled "Infectious Diseases"; aged 53; died, November 2, in Ann Arbor, Mich., of pulmonary and cerebral abscesses.

George Dorsey Green, Lock Haven, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the Medical Society of the State of Pennsylvania; past president of the Clinton County Medical Society; served during the World War; on the staff of the Lock Haven Hospital; aged 66; died, October 15, in the University of Pennsylvania Hospital, Philadelphia, of carcinoma of the pancreas.

John Joseph Maria Carey, Brooklyn; Long Island College Hospital, Brooklyn, 1908; member of the Medical Society of the State of New York; aide to Governor Lehman and formerly aide to President Franklin D. Roosevelt when he served as governor of New York; on the staffs of the Norwegian and Victory Memorial hospitals; served during the World War; aged 58; died, October 1.

Edward Everett Hicks, Brooklyn; University of the City of New York Medical Department, 1893; formerly assistant

clinical professor of neurology at the Long Island College of Medicine; member of the American Psychiatric Association; on the staff of the Kings County Hospital and the Brooklyn State Hospital; aged 69; died, October 18, of cerebral hemorrhage and arteriosclerosis.

Julius Burson Cooper ☉ Birmingham, Ala.; Chattanooga (Tenn.) Medical College, 1904; veteran of the Spanish-American War; was trustee of the Snead Junior College and Wesleyan College; on the courtesy staff of the Norwood Hospital and of the South Highlands Infirmary; aged 63; died, October 19, in the Veterans Administration Facility, Hines, Ill., of carcinoma of the pancreas.

Arthur Lynn Anderson, Springfield, Mo.; University Medical College of Kansas City, Mo., 1900; fellow of the American College of Physicians; served during the World War; on the staffs of St. John's Hospital, Burge Hospital and Springfield Baptist Hospital, Springfield, and the Missouri State Sanatorium, Mount Vernon; aged 65; died, October 25, of cerebral hemorrhage.

Edward John Lawrence, Spokane, Wash.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1908; member of the Washington State Medical Association; served during the World War; formerly member of the school board; on the staffs of the Sacred Heart, Deaconess and St. Luke's hospitals; aged 57; died, September 13, of acute coronary thrombosis.

Walter Harry Hassed, Lusk, Wyo.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1908; member of the Wyoming State Medical Society; formerly secretary and state health officer, Wyoming State Board of Health, and secretary of the state board of medical examiners; aged 56; died, September 23, of a self-inflicted gunshot wound.

Edward Clement Davidson, La Fayette, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; member of the Indiana State Medical Association; fellow of the American College of Surgeons; for many years county coroner; on the staffs of St. Elizabeth's and Lafayette Home hospitals; aged 73; died, October 7.

Lane Bruce Kline, Houston, Texas; George Washington University School of Medicine, Washington, D. C., 1907; formerly a medical missionary; served during the World War; formerly health officer; at one time with the Veterans Administration; aged 59; died, September 30, in the St. Joseph Hospital of heart disease.

Herbert Mott Bentley, Sterling, Kan.; Hahnemann Medical College and Hospital, Chicago, 1897; served during the World War; was a member of the board of education; formerly mayor and vice president of the state board of health; aged 68; died, August 28, in Lawrence of cerebral hemorrhage and arteriosclerosis.

Rudolf Freimuth Teschan, Milwaukee; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; during the World War served as a medical examiner; formerly on the staff of the Evangelical Deaconess Hospital; aged 63; died, October 7, of coronary heart disease.

Frank Albert Davis, Hampton, N. H.; Boston University School of Medicine, 1898; member of the Massachusetts Medical Society; served during the World War; formerly associated with the Veterans Administration; aged 74; died, October 8, in Washington, D. C., of acute cardiac dilatation and chronic myocarditis.

Francois Louis Hughes ☉ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1898; fellow of the American College of Surgeons; served during the World War; on the staff of the Women's Homeopathic Hospital; aged 62; died, October 14, in the Hahnemann Hospital of coronary thrombosis.

Ralph Carleton ☉ Springfield, Mass.; Harvard Medical School, Boston, 1894; member of the American Academy of Ophthalmology and Otolaryngology and the New England Ophthalmological Society; on the staff of the Springfield Hospital; aged 70; died, October 26, of coronary thrombosis.

Howard Meng Lanham, Marshall, Texas; Jefferson Medical College of Philadelphia, 1896; member of the State Medical Association of Texas; served during the World War; aged 66; died, October 7, in the Veterans Administration Facility, Gulfport, Miss., of arteriosclerotic heart disease.

Clermont E. Park ☉ Parkersburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1905; veteran of the Spanish-American and World wars; on the staffs of the Camden-Clark Memorial Hospital and St. Joseph Hospital; aged 69; died, October 10, of chronic myocarditis.

John Ross Smith Martin ☉ Philadelphia; University of Maryland School of Medicine, Baltimore, 1904; served during the World War; aged 58; for many years on the staff of the Graduate Hospital of the University of Pennsylvania, where he died, October 9, of carcinoma of the colon.

Henry Anthony Baker, Kansas City, Mo.; University of California Medical Department, San Francisco, 1891; member of the Missouri State Medical Association; medical director of the Kansas City Life Insurance Company; aged 70; died, September 17, of acute coronary thrombosis.

George E. Denny, Madison, Ind.; University of Louisville (Ky.) Medical Department, 1893; member of the Indiana State Medical Association; formerly superintendent of the Muscatatuck Colony for feeble-minded; at one time member of the state legislature; aged 70; died, October 29.

Fred Paul Weltner, Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1915; member of the West Virginia State Medical Association; served during the World War; aged 51; died, August 15, of coronary thrombosis, diabetes mellitus and fracture of the left arm.

Edward Bogard ☉ Outwood, Ky.; Barnes Medical College, St. Louis, 1904; member of the Washington State Medical Association; served during the World War; on the staff of the Veterans Administration Facility; aged 60; died, October 28, in Louisville of coronary occlusion.

Solomon Simmons Barnett, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1886; member of the Medical Society of the State of New York; aged 77; died, October 30, in St. Luke's Hospital of carcinoma of the bladder.

Herbert Eugene Simrell, Clarks Summit, Pa.; Medico-Chirurgical College of Philadelphia, 1906; served during the World War; aged 59; died, September 28, in the Veterans Administration Facility, New York, of arteriosclerotic heart disease and prostatic abscess.

Herbert Windham Hewitt ☉ Detroit; Detroit College of Medicine, 1903; formerly assistant clinical professor of surgery at his alma mater; fellow of the American College of Surgeons; on the staff of the Grace Hospital; aged 65; died in October of coronary thrombosis.

Arthur Francis Barrett ☉ Jersey City, N. J.; Long Island College Hospital, Brooklyn, 1919; aged 46; formerly on the staff of the Margaret Hague Maternity Hospital and St. Francis Hospital, where he died, October 13, of hypertensive cardiovascular disease.

Robert George Cavanagh ☉ Muskegon, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; for many years on the staffs of the Hackley and Mercy hospitals; aged 82; died, October 29, of chronic myocarditis and arteriosclerosis.

Fred Browne Grosvenor, Columbus, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1911; served during the World War; aged 55; died, October 9, in the Veterans Administration Facility, Wood, of arteriosclerotic heart disease.

Hiram Jackson Clark ☉ Excelsior Springs, Mo.; Washington University School of Medicine, St. Louis, 1907; past president of the Clay County Medical Society; formerly member of the city council; aged 72; died, October 2, of coronary heart disease.

Lucy Winchell Pine, Washington C. H., Ohio; Laura Memorial Woman's Medical College, Cincinnati, 1897; member of the Ohio State Medical Association; aged 75; died, October 6, in the Harding Sanitarium, Worthington, of cerebral arteriosclerosis.

William H. Kunsman, Morrisville, Pa.; Jefferson Medical College of Philadelphia, 1884; for many years justice of the peace and county coroner; aged 81; died, October 6, in the Mercer Hospital, Trenton, N. J., of cerebral hemorrhage.

John Bennett Jr., Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1898; aged 72; died, October 6, in the Presbyterian Hospital of hypertension, cerebral embolus and hypertrophy of the prostate.

Samuel Sidney Foss, Jeffersonville, Ind.; University of Louisville (Ky.) Medical Department, 1886; member of the Indiana State Medical Association; served during the World War; aged 76; died, October 5, of heart disease.

Victor B. Parowski, Detroit; Loyola University School of Medicine, Chicago, 1918; served during the World War; aged 47; died, October 1, in the Mercy Hospital, San Diego, of pulmonary, laryngeal and intestinal tuberculosis.

Charles Cecil Barr ☉ Tilden, Neb.; Sioux City (Iowa) College of Medicine, 1907; fellow of the American College of Surgeons; medical director and owner of the Tilden Hospital; aged 56; died, September 29, of heart disease.

Alfred Oliver Gery, East Greenville, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; aged 75; was killed, October 12, when struck by an automobile.

John Ashby McElwain, Schenectady, N. Y.; Albany Medical College, 1911; member of the Medical Society of the State of New York; served during the World War; aged 55; died, October 6, of coronary sclerosis.

Gilbert Emmings Eddy, Heidelberg, Miss.; University of Alabama School of Medicine, 1907; member of the Mississippi State Medical Association; formerly mayor of Heidelberg; aged 56; died, October 5, of uremia.

Henry Edward Parry, Los Angeles; Hahnemann Medical College and Hospital of Philadelphia, 1893; served during the World War; on the staff of the Veterans Administration Facility; aged 69; died, August 27.

Robert Herschel Geer, El Paso, Texas; University of Texas School of Medicine, Galveston, 1913; member of the State Medical Association of Texas; aged 54; died, October 10, of carcinoma of the liver.

Louis Disler, Canandaigua, N. Y.; St. Louis University School of Medicine, 1936; on the staff of the Veterans Administration Facility; aged 28; died, October 8, following an operation for appendicitis.

Fred Puleston, Daytona Beach, Fla.; State University of Iowa College of Medicine, Iowa City, 1901; member of the Florida Medical Association; aged 75; died, October 7, of cerebral thrombosis.

Alexander Park Boag ☉ Clearfield, Pa.; Temple University School of Medicine, Philadelphia, 1934; aged 32; on the adjunct staff of the Clearfield Hospital, where he died, October 4, of neuronitis.

Lauris Blake Baldwin, Los Angeles; Northwestern University Medical School, Chicago, 1894; veteran of the Spanish-American and World wars; aged 70; died, October 6, of chronic myocarditis.

John Newton Campbell, Varnville, S. C.; Medical College of the State of South Carolina, Charleston, 1908; aged 62; died, October 15, in the Tri-County Hospital, Orangeburg, of coronary thrombosis.

Martha Magdeline Schaplowsky, Worcester, Mass.; University of Kansas School of Medicine, Kansas City, 1937; aged 40; died, September 14, in Denver of acute myelogenous leukemia.

Cassius H. Fullinwider, Mount Vernon, Ind.; Medical College of Ohio, Cincinnati, 1883; member of the Indiana State Medical Association; aged 86; died, October 11, of arteriosclerosis.

Louis Coblin, Anchorage, Ky.; Miami Medical College, Cincinnati, 1876; aged 88; died, October 2, in the Norton Memorial Infirmary, Louisville, of a fractured hip received in a fall.

John Marcus Koelle, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1901; aged 63; died, October 1, of chronic myocarditis.

George Middleton Irwin ☉ Lansdale, Pa.; Jefferson Medical College of Philadelphia, 1933; aged 33; died, October 9, at Bridgeport of tuberculosis.

Isaac Hollen Taylor, Springfield, Ill.; Rush Medical College, Chicago, 1871; aged 90; died, September 27, of coronary occlusion and arteriosclerosis.

Charles Birdsall Pearson, Anaheim, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; aged 77; died recently.

Effie C. Munro Paul, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1893; aged 70; died, September 30, of carcinoma.

Harold Eugene Sheldon ☉ Troy, N. H.; Boston University School of Medicine, 1936; aged 40; died, September 25, of carcinomatosis.

Charles J. Meyer, Denver; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1874; aged 87; died, October 13, of cerebral hemorrhage.

Cicero F. Faulkner, Whitney, Texas; Louisville (Ky.) Medical College, 1898; aged 70; died, October 11, of carcinoma.

Bureau of Investigation

TWO "BUST DEVELOPERS" CEASE DEVELOPMENT

1. Curtis A. Davis and His Personal Collection of Fraud Orders

2. Gloria Mauro's "Firmform" Not so Firm

"Bust developers," whether in the form of mechanical devices, massage creams or internal treatments, have again and again been debarred from the mails by the Post Office Department. Though some promoters may have closed up shop, one notorious offender has repeatedly dodged the government's edicts against him.

The Davis-Cook Swindle

In this department of THE JOURNAL, March 5, 1938, appeared a discussion of the Post Office fraud order issued in July 1937, which debarred from the mails the Youth-Aid Products of Los Angeles. The article showed that this was a new name adopted by an old-time swindling outfit, the Jennie L. Cook Company, to circumvent a similar fraud order that had been issued against the same promoter in January 1936. The article further brought out the facts that the Curtis A. Davis who was the moving spirit in this concern had originally promoted other mail-order swindles from Chicago, that the first fraud order had been issued against him as long ago as August 1916, and that he had evaded it by changing most of the firm names under which he had been doing business, so that the Post Office found it necessary to issue a supplementary fraud order against him in January 1917 to cover these new names.

In time Davis transferred his nefarious activities to Los Angeles. According to the Post Office he once stated that he used the title "Jennie L. Cook Company" because Jennie L. Cook was the name of his sister, who lived next door to the rooming house from which he conducted his business, but he claimed she had no financial interest in the fraud. The Cook trade style was one he had long employed in his Chicago schemes.

In 1932 another government agency, the Federal Trade Commission, issued a Cease and Desist Order against Curtis A. Davis, trading as the Jennie L. Cook Co., Los Angeles. In this Curtis was ordered to (1) cease advertising as a woman; (2) cease implying in his advertising that the statements he made were from one woman to another; (3) cease claiming that the Jennie L. Cook Company was composed of Parisian beauty culturists; (4) cease advertising that the Cook "treatment" was scientific, was made from a French formula and was a constitutional vitalizer and a tissue builder; (5) cease claiming that by the use of the "treatment" a perfect figure could be developed and the human body could be properly proportioned, and (6) cease claiming that the "treatment" would fill up hollows in the body, give the user strength and remove wrinkles. The facts were briefly noted in this department of THE JOURNAL, April 30, 1932.

Considering Davis's record in quackery, it was hardly to be expected that he would regard this latest pronouncement from the government too seriously. Hence it is not surprising that his name bobbed up again in 1936 in a Post Office fraud order and in 1937 in another, which was later supplemented by still another fraud order. The fact is that the Federal Trade Commission itself was obliged to bring a second action against Davis, as the result of which it announced on Nov. 25, 1939, that it had got him to sign a stipulation promising to discontinue certain lies in his advertising. Among these were that his "Jane Cook's Wonder Tissue Creme" will furnish nourishment to the tissues or cells or increase the size of the bust, or that a flat chest is due to a lack of nourishment in the tissue cells of the chest or to the fact that in a case of flat chest the cells are shrunken or collapsed. Davis further agreed to cease representing that his product was in fact a "tissue" cream, either by using that word in the name of a product or otherwise. A New York concern which handled advertising for Davis also was prevailed on to promise similarly to withdraw these false claims for the nostrum.

But Davis, with the brazenness of a habitual law-breaker, continued to defy governmental restraints on his swindles. A new name, The Alvin Sales Co., entered the picture as Davis's latest

trade style. Again the Post Office made an investigation, which revealed that Davis's latest exploitation, the "Jane Cook Beauty Aids," included his old "bust developer" fraud, that the latter was now being put out as the "Jane Cook Method" and that it consisted of the "Wonder Tissue Creme" and "Wonder Tonic Tablets," these last for internal use. A government chemist testified that the cream was made up of wool fat, fatty oil, a minute amount of ash and 28 per cent of water and that each tablet contained 1 grain of ferrous carbonate with alkaloids, including brucine and strychnine amounting to about one-sixth grain of nux vomica. One tablet was to be taken twice daily and the cream was to be massaged on the breasts. As medical evidence introduced at the Post Office hearing showed that this combination treatment would produce practically none of the effects on the breasts claimed in Davis's advertising and that the preparations in question were practically identical with those named in previous fraud orders, a new one was issued against the names Curtis A. Davis, C. A. Davis, Jane Cook Method and Alvin Sales Co. on March 2, 1940, and postmasters were instructed to return to all senders when known (or when not known, to send to the Dead Letter Office) all letters addressed to the names given.

But soon afterward Davis again was found to be evading the fraud order, once more using a new name, "Mrs. J. Cook," under which title he continued to solicit prospective victims with literature on his "Wonder Tonic Tablets" and "Jane Cook's Massage Creme" for the development of the female figure. Hence on the recommendation of Judge Vincent M. Miles, Solicitor for the Post Office Department, on March 14, 1940, the recently issued fraud order was extended to cover the name of Mrs. J. Cook, Los Angeles.

Thus Davis and the Post Office seem to be engaged in one continuous bout of many rounds. Of course, there ought to be some way to terminate the necessity for such repetition of effort on the part of the Post Office Department in protecting the public. But since there apparently is no such mechanism, one can only hope that the postal authorities will not become disgusted or discouraged about the whole thing. After all this may help the unemployment situation at least as far as the Post Office Department is concerned. In these parlous times such accounts as this help to add to the gaiety of reflections on our government's legal activities.

The Gloria Mauro Fraud

Another "bust developer" swindle which emanates from Los Angeles was promoted as a "bust normalizer"—to build up underdeveloped breasts to normal size or to restore enlarged or sagging breasts to their former contour. This business was conducted by one John Frank Mauro operating under the names Gloria Mauro, Gloria Mauro Products and Gloria Mauro Company. It is reported that he started his scheme in Hollywood in December 1936 and also established an eastern sales agency in New York which eventually was discontinued. It appears that some time in 1937 Mauro, accompanied by his wife, went to Belgium and still resides there. Prior to going, it is said, he gave one Florence Whittle power of attorney to act as his legal representative and to continue the business in his absence.

The Post Office Department properly looked into Mauro's swindle and in a memorandum on the case Hon. W. E. Kelly, Acting Solicitor, brought out the foregoing facts and some others. He showed that neither Mauro nor Miss Whittle possessed any medical training or employed a physician or any one else possessing medical knowledge. The "treatment," a device known as the "Gloria Firmform," was described in the memorandum as follows:

The "Gloria Firmform," which costs the promoter \$3.50 to manufacture, is a metal, cup-shaped apparatus designed to fit over the breast. Attached to the top is a rubber hose to be connected with a water faucet. Water entering the device through the hose is expelled upon the base of, and about the breast in numerous, needle-like sprays. Leading from the apparatus is a metal outlet for water introduced therein by the hose. Directions for use sent with the device read in part as follows:

"The Gloria Firmform is ready for use when taken from the package. In using, simply attach the hose connector to any convenient cold water faucet. Press the Firmform snugly against the body, covering the breast, and with sufficient firmness to prevent water seepage around the rim. Turn on the water with the fullest force available. . . . The length of time required and the degree of success attained varies, of course, with the degree to which the breasts are underdeveloped, have sagged, aged, condition of health and size of

breasts. However, the tonic effect will be noticed quickly and two or three weeks' regular use of Firmform usually indicate the beginning of improvement that convinces the user that she should follow the directions faithfully until the bust fills, firms and assumes the contours so greatly desired by every woman.

"FOR DEVELOPMENT"

"The woman with flat, underdeveloped breasts, if in normal health, need not usually despair of ever being beautiful of form . . . of having the lovely, full, firm-pointed breasts that so few women have and yet so many could develop with the proper method and care."

The memorandum went on to show that, according to expert medical testimony in the case, the only effect which this device could produce if used according to the directions furnished would be a stimulation of the skin overlying the breasts through the action of the cold water, thus temporarily increasing the circulation of the blood in that region. This testimony showed, further, that the size, shape and contour of the female breasts depend on the amounts of fat and the glandular and fibrous tissues deposited within them. Hence the application of cold water by means of the "Gloria Firmform," even over a long period, would have no effect whatever on the physiologic factors that determine the amounts of these fatty and glandular tissues in the breasts. Further, fatty depositions in the breasts of these persons naturally would cause sagging or pendulous breasts and the mere application of cold water to the overlying skin of these organs could not correct their sagging.

Some of the expert medical testimony referred to in the memorandum aptly summarizes the worthlessness of such a treatment as follows:

" . . . in order to accomplish the promised results in both these types of cases, the temporarily increased flow of blood brought about by the cold water principle of the 'Gloria Firmform' would, in the one case, have to bring about an increased deposition of fat cells, and of glandular and fibrous tissues, and in the other, accomplish the diametrically opposite effect of removing the excess fatty and other deposits responsible for the sagging, pendulous condition. According to the medical evidence, neither the 'Gloria Firmform' nor any other single, uniform method of external treatment can operate to produce such opposing results."

The fraud order against Gloria Mauro, Gloria Mauro Company and Gloria Mauro Products was issued Nov. 3, 1939.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ARTIFICIAL LIGHTING AND WINDOWLESS BUILDINGS

To the Editor:—The National Defense Commission has many million dollars' worth of contracts pending for industrial buildings. In designing these the architects have attempted to make them of a "blackout" type. One way of doing this is to use windowless structures equipped completely with artificial light and air conditioning. Have you run across any industrial health reports, either from this country or from England, which would throw light on these questions: 1. Does the long time use of artificial light to the exclusion of natural light have any harmful effect on the eyes of workers? 2. Do windowless factories cause claustrophobia among workers? In case of an air raid would panic be more prevalent among workers in windowless buildings than in glazed buildings? (If there are any studies on claustrophobia among submarine crews, these might help answer this question.) 3. What effect does work in air conditioned windowless factories have on the sickness rate of employees? (We have seen some reports on health in air conditioned offices but don't recall any on health in air conditioned, windowless factories.)

W. G. Hazard, Toledo, Ohio.

ANSWER.—No one of these questions can be answered categorically and without recognition that many circumstances other than the exact ones mentioned influence the situation.

1. The long time use of artificial lighting to the exclusion of all natural light may have a harmful effect on the eyes of workers, but foremost because of the inadequacy or unsuitability of the artificial lighting provided. Until recently there has been no form of artificial lighting that compared favorably with daylight. Even now statements as to parity must be accepted with reserve. S. W. Fisher (*Lancet* 1:668 [April 6] 1940) compares the total incidence and incident rate of miners' nystagmus, which long has been England's foremost occupa-

tional disease, for the years 1930 to 1938 inclusive. In the first mentioned year, 3,066 new cases of miners' nystagmus appeared, constituting a rate per thousand of 4.15, while in 1938 the total number of new cases was 1,019, which provided a rate of 1.66. The only difference in work conditions has been the introduction of better illumination. The essence of this comment is that inadequate artificial illumination is the basis for nearly all unfavorable comparisons between natural and artificial lighting. In England, Patmore (*Indust. Welfare* 21:387, 1939), writing of efforts to meet the requirements of defense lighting, points out the necessity for high standards of illumination in order even to approach daylight and recommends high pressure mercury vapor lamps. This author notes that visual acuity is greater with this form of artificial illumination, in contrast to the tungsten lamp, in which it is stated that the maximum output is in the infra-red band, to which the visual apparatus of the eye is little responsive. The Industrial Health Research Board of England's Medical Research Council, in its first emergency report, entitled "Industrial Health in War," notes that some fine industrial work, particularly in persons with trivial eye defects, cannot be done with the best of lighting unless special optical aids are provided. Such operations call for industrial magnifiers, binoculars and at times the provision of corrective lenses for otherwise negligible deficiencies. It is now known from the work of Ferree and others (*Persomel Journal* 14:18 [May] 1935) that the illumination requirements for various age classes of persons are different. Thus a youthful group might attain a high level of acuity at 10 foot candles without any definite increase with augmented lighting. This is not true for workers of middle and early old age, whose lighting requirements are on a different level. With the advent of fluorescent lighting, with high intensity, absence of glare and a minimum of disturbing shadows, it is now possible to meet all the visual requirements of daylighting, but while artificial illumination may be made the equal or even the superior of daylight in selected enterprises, such as department store work, it should not be inferred that all the beneficent purposes served by sunlight are met.

2. Current comment on windowless air conditioned work places implies that such structures are radically new. Overlooked is the fact that most theaters are windowless, ventilated or air conditioned creations and that the counterpart of a windowless ventilated factory can be found in any mine. At this time every factory in Great Britain and other portions of the warring world has been made into a semiwindowless affair through the requirements of the blackout, much of which is described in the British Home Office Factory Department Publication entitled "Factory Ventilation in the Blackout." It is common experience that claustrophobia is not of common occurrence among theater patrons. On the other hand, few persons enter a mine or descend into a well without some anxiety. Claustrophobia is not a disease entity and certainly the mild apprehension which is the lot of most persons confronted with strikingly unusual physical surroundings cannot be regarded as significant. On moving into any new factory or office quarters of the windowless or opaque glass tile type of structure, fair numbers of all employees become more aware of air conditions, lighting and odors. In Detroit the Detroit Edison Company lately has constructed a large office building of highly modern design, completely air conditioned, with opaque glass tiles, permitting the entry of light but preventing any vision from within or without. During the early months after occupancy there arose many complaints from older women, and particularly scrub women working at night, protesting against being "put in a box." All such apprehension disappeared after a few months. In England this sort of situation has become associated with "gas obsessions." Owing to numerous breaks in gas lines there has been some warrant for anxiety on entering closed spaces. However, anxiety hysteria about gas dominates the picture. Usually these mild states are transitory and unimportant. When the anxiety is severe or prolonged, adequate inquiry ordinarily will establish causative connections wholly unrelated to physical surroundings. Among psychoanalysts the belief holds that all phobias, such as claustrophobia and agoraphobia, always represent an unconscious feeling of guilt resulting from an early disagreeable memory.

3. The intent of this comment is to recognize the possibility of a little "jumpiness" on the part of workers newly moved into windowless air conditioned work places but to deny the probability of creating any significant pathologic state by this type of architecture. When disturbing anxiety arises, fundamental causes should be sought in other places than windowless walls. See War Neuroses (London Letter, *THE JOURNAL*, Feb. 3, 1940, p. 424). In the case of submarine crews, the numerous excitants to anxiety preclude any possibility of segregating claustrophobia as an entity.

ALLERGIC SHOCK

To the Editor:—A man aged 37 of western Kansas was recently admitted to a local hospital complaining of numbness and tingling of the hands and feet and acute erythema, weakness, nausea and vomiting of about four hours' duration. The first attack was noted by the patient five years ago, during which he became dyspneic and cyanotic and fainted. He had severe substernal pressure with the first attack but has not had such a symptom since. He has about one or two attacks a year, usually in the spring and fall, and each attack is more or less typical. It begins with an erythema and a generalized sensation of warmth, which gradually increases and deepens to a maximum in anywhere from one-half hour to thirty-six hours. Attacks are always attended by severe bronchial secretion which is clear and contains no pus, also by nausea and vomiting. The present attack was the first in which he had numbness and tingling of the hands and feet. He has no pain during these attacks but usually has a slight headache for the following twenty-four hours. He is sick on the second day but is usually well and able to return to work by the third day. He has had chills and fever with each attack. He has had extensive laboratory studies and investigation from the standpoint of allergens, blood and urinalysis, gallbladder and gastrointestinal tract, x-ray and fluoroscopic studies, all of which have been normal. Extensive cutaneous tests were normal except for reaction to a few foods to which the patient showed sensitivity and which he has since avoided. When first seen by me the patient had an acute generalized erythema, his blood pressure was 60 systolic, 30 diastolic, and his pulse was rapid and thready. The skin, however, was hot and moist, and the patient was chilling vigorously and complained of being cold. He was given the supportive measures for shock and responded well, so that in about thirty minutes he felt much better and his nausea and vomiting had subsided to a mild degree. During the vomiting he regurgitated some undigested potato which he had eaten some ten hours previously. Urinalysis was not remarkable except for a heavy trace of albumin and numerous hyaline and granular casts. The white blood cell count was 13,550 with a normal differential. I suspected an allergic reaction, possibly a histamine-like reaction, as the cause of the condition, but I was not able to make a diagnosis and the patient states that his family physician has never arrived at a diagnosis. I should like to have an opinion as to the cause of this syndrome and would appreciate any suggestions you may have as to its treatment. M.D., Colorado.

ANSWER.—This interesting case offers a real diagnostic problem. The fall in blood pressure and other symptoms indicate the presence of some form of shock, although in shock fever and leukocytosis are not common. Since the attacks occur at long intervals and last only two or three days, and since there is complete freedom from symptoms between attacks, one is forced to conclude that there is no organic disease. Therefore the patient must have some nonorganic trouble or must be poisoned by some food. Food poisoning is possible although not likely.

A severe allergic reaction with shock is probably present. In favor of this diagnosis are (1) the severe bronchial secretion, (2) the erythema (pruritus is often associated), (3) the acuteness of the onset, (4) the relatively short duration and (5) the fall in blood pressure. Eosinophilia of the blood and sputum are usually present but are not necessary to make the diagnosis. Fever is uncommon, but can occur in severe allergic conditions.

Granted that the patient is allergic, it seems likely that the cause of the attacks is some substance to which the patient is exposed infrequently. This could be a food which he eats rarely or could be some inhalant, e. g. horse dander, dog hair, orris root (perfume) or perhaps a drug, such as acetylsalicylic acid, quinine or some hypnotic. Tests should be made both cutaneously and intracutaneously not only for the common antigens but also for the rare ones, e. g. karaya gum (wave set), Brazil nuts, mango and artichokes. Cutaneous tests for drugs are unsatisfactory. Instances of severe allergic shock to rare antigens are not uncommon and death has occurred occasionally from such substances as peanut butter, poppyseed, Brazil nuts, glue or some drug. The patient should keep a food record and should also record any unusual exposures to animals, drugs or the like. Epinephrine should be administered for any further attacks.

TONSILLECTOMY AND HEMORRHAGE PREVENTION

To the Editor:—I have told a family that outside of seeing that a child is in the best physical condition, and provided the coagulation time is normal, there is nothing to be given preoperatively to prevent bleeding in a tonsillectomy, should the technic be good. A relative's doctor has informed them that I was wrong. Consequently for the family's benefit I would appreciate it if you would reply to this question.

Sidney Schreiber, M.D., Forest Park, Ill.

ANSWER.—This question has been the subject of many discussions, conferences and literary contributions by laryngologists all over the world. The advice given is basically sound and is the method used by the majority of specialists. Indeed, many men do not even have the coagulation time taken unless the history warrants it. The essential points are a good history, physical examination and the drawing of inferences and conclusions as to the operative fitness and condition of the child.

If the history is such as to suggest an inquiry into the possibility of postoperative hemorrhage, then appropriate blood studies

should be made including coagulation, bleeding time and platelet count. Though such studies are important, it must be remembered that they are often not reliable, and too much attention should not be paid to them. Where the observations fall far below normal, certain precautions may be undertaken preoperatively. Parenteral injection of small amounts of horse serum or whole blood, or even larger amounts of blood by transfusion when anemia is also present, may be employed to shorten coagulation or bleeding time. Where serum is employed, allergic sensitivity must be ruled out, although the principle of sensitization to a foreign protein (requiring about ten days) has been suggested as a means to prevent the occurrence of hemorrhage in hemophilia by subsequent intradermal administration of the protein to increase the coagulability of the capillary blood. The intradermal injections do not desensitize the patient. In thrombocytopenic purpura, blood transfusion is an effective means of restoring the platelet count to normal or near normal. Even in hemophilia surgery can be safely undertaken if transfusions are given during the operation and healing period, to hold the coagulation time near normal. The use of blood or serum as prophylaxis against hemorrhage is probably more effective than the use of calcium salts, estrogens and placental or other tissue extracts. The Council on Pharmacy and Chemistry has not accepted for New and Nonofficial Remedies any of these preparations as effective prophylactic agents against hemorrhage, except nonimmune horse serum. Thromboplastic substances are recognized by the Council for local use in the treatment of hemorrhage from oozing surfaces, as is also the use of iron compounds for their styptic or astringent properties. The Council has deferred consideration of the use of snake venom as a parenteral hemostatic agent in the treatment of hemorrhagic conditions because of the meager evidence available. The experience recently reported concerning the effectiveness of Koagamin (a compound containing oxalic and other dicarboxylic acids derived from the plant shepard's purse) as a prophylactic parenteral coagulant is insufficient to warrant more than experimental use until further evidence becomes available. Some years ago the Council declared Styptsate, another proprietary hemostatic prepared from shepard's purse, not acceptable for New and Non-official Remedies.

Each case requires individual study, observation and evaluation and must be dealt with accordingly. There are a number of eminent laryngologists who hold exactly the same opinion that has been expressed by the inquirer.

DURATION OF POSITIVE BENZIDINE TEST AFTER GASTROINTESTINAL BLEEDING

To the Editor:—A question arose on ward rounds as to the duration of the positive guaiac or benzidine test on the stool after the cessation of active bleeding in the gastroduodenal region and elsewhere in the gastrointestinal tract. References would also be appreciated.

Victor F. Lief, M.D., Far Rockaway, N. Y.

ANSWER.—The figures given by various authors for the average duration of a positive benzidine test for occult blood in the stool following hemorrhage from a peptic ulcer are in general agreement. This period was 13.6 days in eighty cases recently reported by Turnbull and Sagi (*Am. J. Digest. Dis. & Nutrition* 6:92 [April] 1939). Meulengracht (*Lancet* 2:1220 [Nov. 30] 1935) found that an average of 13.4 days with 4.5 defecations elapsed before the stools were entirely negative with Gregersen's benzidine test on the "old form" of treatment of bleeding peptic ulcers and that an average of 10.2 days elapsed with 4.8 defecations when the Meulengracht treatment was employed. The latter group consisted of 251 cases. The difference of approximately three days in the duration of positive benzidine reactions was not taken as an indication of a shorter period of bleeding. Noth and Wilbur (*Proc. Staff Meet., Mayo Clin.* 10:824 [Dec. 26] 1935) found the average duration of a positive benzidine reaction in five cases to be ten and a half days from the time of admission. Presumably hospitalization was soon after the onset of hemorrhage. It should be noted that figures for average duration are not directly applicable to an individual case. Schiodt (*Am. J. M. Sc.* 193:313 [March] 1937) gives the average time as 13 plus or minus 2.5 days. In individual cases his tables (p. 327), however, show that the variation was from five to forty-four days.

Since the passage of food through the gastrointestinal tract requires considerably less time than from ten to fourteen days, the question arises as to whether the hemorrhage usually extends over a period of days. Meulengracht (*Brit. M. J.* 2:321 [Aug. 12] 1939) believes that "actual bleeding as a rule can last only a short time, perhaps only a few hours," and that the prolonged positive benzidine test is an indication of the time required for the intestine to rid itself of blood rather than an

indication of the duration of hemorrhage. In support of this view Meulengracht cites the work of Hesser (*Acta med. Scandinav.* supp. 59, p. 367, 1934) that patients with bleeding peptic ulcer gave evidence of having barium salts in their stools for from eight to twenty-one days following a barium sulfate meal.

Although a single hemorrhage of not more than a few hours duration may be the rule in peptic ulcer, it does not exclude the possibility that in some cases the bleeding may be more prolonged or may recur, as evidenced by the vomiting of bright red blood several days after the initial hematemesis or melena. However, the average figures are of value in an individual case in that when the stools become negative with the benzidine test it is known that the bleeding probably stopped from seven to fourteen days before.

Hemorrhage from lesions in the gastrointestinal tract other than that from peptic ulcers and esophageal varices is apt to be prolonged and with an indefinite termination. This applies particularly to hemorrhage arising in lesions of the colon. It is therefore extremely difficult to determine the duration of a positive benzidine test after the hemorrhage has ceased; however, it seems reasonable to think it would be somewhat less than that in hemorrhage from peptic ulcers.

BILATERAL PNEUMOTHORAX AND INTRA-ABDOMINAL SURGERY

To the Editor:—A woman aged 50 has bilateral pulmonary tuberculosis for which she is receiving bilateral pneumothorax therapy. At present her sputum is negative and the pulse rate and temperature are normal. She also has been having severe attacks of pain in the right hypochondrium presumably due to gallbladder disease. She has not responded to diet and medication. X-ray studies of the gallbladder have not been made. If further examination reveals the condition to be due to cholecystitis or cholelithiasis, would surgery be contraindicated because of the presence of bilateral pulmonary tuberculosis? If surgery is contraindicated, what alternative therapy would you suggest for the gallbladder condition?

Daniel Haffron, M.D., Elgin, Ill.

ANSWER:—Artificial pneumothorax, even bilateral artificial pneumothorax, is not an absolute contraindication to urgent abdominal surgery. Such surgery should be resorted to only when there is an urgent indication and when the diagnosis of abdominal disease is absolutely certain and specific. Patients with pneumothorax frequently have pleuritic pain which radiates into the upper part of the abdomen and which may even cause localized tenderness and spasm.

The patient in question might be operated on at the present time only if x-ray studies give certain evidence of the diseased gallbladder and the attacks are so frequent and severe as to threaten complications and as to be unendurable.

THREATENED ABORTION

To the Editor:—A woman aged 31 was not able to conceive for seven months. A basal metabolic test showed —17; the pulse was 60, blood pressure was 96 systolic, 60 diastolic, the Wassermann reaction negative. Thyroid substance from one-half to 3 grains (0.03 to 0.2 Gm.) was prescribed. At the time the next period was expected the patient complained of pains low in the abdomen, typical of the menstrual period. After six days of intermittent cramps and no showing of the period (the patient claimed a variation of only one to three days in the cycle) five daily injections of progesterone of 1 international unit each were given. The cramps subsided. For the first three months of pregnancy the patient had severe nausea and some vomiting. The thyroid dose of from 3 to 4 grains (0.2 to 0.26 Gm.) daily was continued. On entering the fourth month she noticed a bloody discharge of from 1 drachm (4 cc.) to 1 ounce (30 cc.). The patient was advised to take bed rest, and 5 international units of progesterone was used daily. She has been in bed for three weeks and the discharge has not diminished. In addition cramps are felt intermittently and at times they are so severe that codeine is necessary. Treatment still consists of 5 international units of progesterone daily, from 3 to 4 grains (0.2 to 0.26 Gm.) of thyroid, and vitamin E administered orally. Her basal metabolism is now —7. Is this therapy satisfactory? Have you any other suggestions? What are the chances of a successful full term pregnancy?

M.D., New York

ANSWER:—The patient has been bleeding continuously for at least three weeks in spite of treatment, so that the present status of the gestation should be determined. It is possible that the treatment has caused a delay in the natural evacuation by the uterus of an abnormal gestation. This is a rather common occurrence at the present time. It is entirely possible that the fetus has been dead for some time and is being retained in the uterus. Rarely a hydatidiform mole may produce a clinical picture such as that described. A hormonal test for pregnancy and a careful vaginal examination will determine whether the gestation is normal.

The management which has been followed in this case represents an example of acceptable therapy. Threatened or habitual abortion may be treated by a sufficient amount of thyroid to

bring the basal rate to normal, progesterone and possibly vitamin E in the form of wheat germ oil. Synthetic vitamin E, alpha-tocopherol, is available for experimental work but is not yet available for clinical use. One must remember that many abortions occur as a result of abnormal embryos or chorions. Of course, it is useless to prolong one of these abnormal pregnancies. Furthermore, the onset of bleeding and particularly its continuation over a period of a week or longer is often indicative of serious damage to the embryo or gestational sac. It is unwise to continue conservative treatment over too long a period for this reason. Recent statistics indicate that if a pregnancy which has threatened to abort continues to term there is no increased likelihood of malformed fetuses.

BUTOLAN FOR PINWORMS

To the Editor:—Since 1924 I have on occasion used butolan in the treatment of pinworm infestations. I used it as recommended in George Blumer's edition of Billings-Forchheimer's *Therapeutics of Internal Diseases*. The results have been uniformly successful and no bad effects have been noticed. (Quassia enemas were used in conjunction.) I now have a patient recovering from postpneumonia empyema who is infested. She is 9 years old. Is there any reason why butolan should not be used? I have never seen it mentioned in *The Journal*.

George Braunlich, M.D., Davenport, Iowa.

ANSWER:—No contraindications for the use of butolan have appeared in the limited literature on this drug; in fact, the users of butolan claim that it has been without any untoward effects.

The articles by Schickhardt (*München. med. Wchschr.* 67: 722 [June 18] 1920) and Francke (*Med. Klin.* 16: 758 [July 18] 1920) were the first to be published on the use of this drug for the treatment of oxyuriasis. They claimed good results but their criteria of cure were based on the alleviation of symptoms and on stool examinations rather than on an anal swab technic, which today is regarded as the most reliable procedure for the diagnosis of oxyuriasis. Other notes and articles apparently have been based on the results of these investigators.

At the present time the drug of choice for the treatment of oxyuriasis appears to be gentian violet given orally, as reported by W. H. Wright and F. J. Brady of the United States Public Health Service (*THE JOURNAL*, March 9, 1940, p. 861).

DIVISION OF SAPHEOUS VEIN IN VARICOSE ULCER OF LEG

To the Editor:—A white man aged 40 had varicose veins injected about ten years ago. A varicose ulcer appeared over the lower third of the same leg nine months ago following the gradual reappearance of the varicose veins. I suggested rest off his feet, which he refused, and he has been since under other doctors' care with various ointments without results. I am wondering whether there is a contraindication for the ligation of the internal saphenous vein because of the presence of the ulcer and also what suggestions can be offered for the handling of this problem.

M.D., Connecticut.

ANSWER:—The high division of the long saphenous vein and its tributaries at the groin is indicated in the presence of a leg ulcer when (1) there is no acute inflammation at the site of the ulcer, (2) acute lymphadenitis is not present in the groin, (3) there is evidence of marked reflux of blood through incompetent valves of the long saphenous vein and (4) there is no evidence of deep venous obstruction. The last contraindication seldom exists, for even if there is a good history of deep thrombophlebitis the thrombus frequently canalizes or is compensated by deep venous collaterals. The ulcer may not heal even after the high division of the saphenous vein and obliteration of the distal segment by injections if there is a severe thrombophlebitic induration surrounding the ulcer. If such is the case, weekly applications of glycerin-gelatin casts may be helpful in softening the induration and healing the ulcer. For resistant ulcers it may be necessary to resort to a major surgical procedure consisting of a wide excision of the fibrosed connective tissue, including the fascia.

SENSITIZATION TO DIGITALIS

To the Editor:—In reference to sensitization to digitalis (*Queries and Minor Notes*, *The Journal*, Sept. 28, 1940, p. 1122) there is little or nothing mentioned about systemic reactions but there are some reports of cutaneous response. A dermatitis may result from the external application of the fresh leaves of foxglove. The ingestion of this drug may cause macular and papular eruptions (Hydel, an erysipeloid eruption (Traube, Schuchardt) and a generalized erythroderma (Morrow, P. A.: *Drug Eruptions*; Selected Monographs in Dermatology, New Sydenham Society edited by T. Colcott Fox, London, 1893). There are a few other old references on cutaneous eruptions from the ingestion of digitalis. The following two are more recent: Pulch, A.: *Montpellier méd.* 73: 235 (April 15) 1930. Brandt: *Dermat. Wchschr.* 103: 726 (June 12) 1937.

E. William Abramowitz, M.D., New York.

Pennsylvania July Report

Miss Marguerite G. Steiner, acting secretary, Bureau of Professional Licensing, reports the written examination for medical licensure held at Philadelphia and Pittsburgh, July 9-13, 1940. The examination covered five subjects and included fifty questions. An average of 75 per cent was required to pass. Four hundred and seventy-two candidates were examined, 450 of whom passed and twenty-two failed. The following schools were represented:

South Carolina June Report

Dr. A. Earle Boozer, secretary, State Board of Medical Examiners of South Carolina, reports the oral and written examination for medical licensure held at Columbia, June 24-26, 1940. The examination covered seventeen subjects and included fifty-two questions. An average of 75 per cent was required to pass. Forty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Loyola University School of Medicine.....	(1940)		81.9
Tulane University of Louisiana School of Medicine.....	(1940)		84.2
Johns Hopkins University School of Medicine.....	(1932)		81

Book Notices

Modern Dermatology and Syphilology. By S. William Becker, M.D., Associate Professor of Dermatology and Syphilology, Kuppenheimer Foundation, University of Chicago, and Maximilian E. Obermayer, M.D., Assistant Professor of Dermatology and Syphilology, Kuppenheimer Foundation, University of Chicago. Cloth. Price, \$12. Pp. 371, with 493 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1940.

Here is a distinctly new volume in the field of textbooks on dermatology. The book has been planned primarily as a textbook and contains several new features both as to arrangement and as to nature of material which will make it appeal to the medical student. The functional point of view has been dominant. Skin diseases are grouped according to common causation or diagnostic considerations which make natural grouping. There is a general consideration of therapy as has been the custom with other textbooks on diseases of the skin, but in addition special information is provided in relationship to each group of diseases. The bibliography for each chapter is brief but useful. There are thirty-two colored illustrations and a great number of illustrations in black and white, which naturally are of special value in a work on diseases of the skin. Another new feature is a chart of the treatment of syphilis worked out according to the technic of the University of Chicago Clinics but guided largely by the decisions of the Cooperative Group. A chart of this type is obviously useful as a guide to the general practitioner. The book is printed in two narrow columns, which make reading easy. The style is direct and the volume has been well edited. This book will constitute not only a textbook for students but also an exceedingly good reference book in its field. The section on syphilis concludes the volume and the section itself is concluded with a discussion of the social aspects of the disease and the public effort against it. This is, of course, unique for a textbook on diseases of the skin and syphilis. Progress in this field has been so rapid that this chapter is well nigh obsolete with its date of publication. A good index completes what is an exceptional volume.

Endocrine Therapy in General Practice. By Elmer L. Serrinhaus, M.D., F.A.C.P., Professor of Medicine, University of Wisconsin, Madison. Third edition. Cloth. Price, \$2.75. Pp. 238, with 49 illustrations. Chicago: Year Book Publishers, Inc., 1940.

This edition includes a number of revisions throughout the various chapters and also a new chapter on the endocrine problems in childhood and adolescence. The book is intended to be an elementary textbook on endocrine therapy. It includes brief discussions of diagnosis and etiology of the various disturbances. The larger portion is devoted to the use of various agents in the treatment of endocrine disorders. The book is valuable in that it explains in a simple manner the many common endocrine disturbances and their treatment. It does not confuse the untrained reader with discussions on atypical and rare disorders but limits itself to cases which the general practitioner is most apt to meet. In this way a clear understanding of endocrine therapy is available for the general practitioner. The book is valuable in that it demonstrates that there is no need to consider endocrine therapy a mysterious, complicated and difficult task if the fundamental principles of physiology are adhered to. On the other hand, the author seems to evince undue optimism toward therapeutic procedures which are still in an experimental stage. The stimulation treatment of the ovaries with the various gonadotropins is still most uncertain, even in the hands of the specialist, and it appears inadvisable to recommend specific treatment to the untrained practitioner with these substances. Certainly the results with pregnant mare serum gonadotropin do not justify its use by the general practitioner. This is reflected in the statement on page 188 that preparations of pregnant mare serum gonadotropin "are probably effective stimulators of testicular tissue growth and function." In addition, the treatment of pituitary dwarfism does not appear to be as promising as the author maintains. In fact, it is surprising that the author considers it possible to overtreat with growth hormone and produce an acromegalic condition (p. 195) when, as a matter of fact, the growth hormone preparations available commercially are notoriously weak. Unfortunately the author

refers repeatedly to proprietary endocrine preparations and the firms which market these products. This procedure aids in the promotion of certain products which may not have been examined and approved by official organizations on pharmaceuticals and, on the other hand, discriminates against other preparations which might be equally effective.

Pathology. By Eugene C. Piette, M.D., Pathologist and Director of the Clinical Laboratories of the West Suburban Hospital, Oak Park, Illinois. Third edition. Cloth. Price, \$2. Pp. 247, with 60 illustrations. Philadelphia: F. A. Davis Company, 1940.

Although the title of this book gives no indication of its purpose, the introduction and text suggest that it is intended for nurses. In addition to a short review of the meaning of terms used in pathology there are also appended directions for collecting, labeling and examining specimens destined for a laboratory of clinical pathology. The appropriateness of writing a pathology for nurses might well be questioned. Possibly they should have their minds and their time fully occupied with their own specialty, without any dabbling in the jargon of the medical sciences. But if modern standards force them to learn the special language of pathologists, then, at least, instruction in this line should be accurate and down to date. This book falls short in both of these requirements. Beginning as a sort of amplified dictionary, it becomes a potpourri of pathologic descriptions, symptoms, treatment and admonitory advice. For example:

Page 20. "If there is a pathologist in the hospital, the nurse must call him immediately after the thyroid is removed."

Page 24. "Vitamin A—antiophthalmic and anti-infective . . ."

Page 39. "Arteriosclerosis is a disease of advanced age . . . In still another case the arteries of the pyloric part of the stomach or duodenum become thickened, hyalinized, and their lumen becomes obliterated while the patient is still in his thirties and shows no other signs of sclerosis. This may cause a peptic ulcer."

Page 42. "Only the stones (in gallbladder) which contain a certain amount of calcium cast a shadow on x-ray examination."

Page 54. "Peptic ulcer (gastric and duodenal), according to a modern conception, is also an infarct."

Page 56. "Frequently this death (from embolism) occurs after slight exertion, sitting up or turning over, against the doctor's orders."

Page 61. "In the temperate zone syphilis is the most important causative agent in local enlargements of an organ such as the leg, scrotum, etc."

Page 93. "This mouth breathing may lead to heart lesions, arthritis, and nephritis."

Page 99. ". . . Infected hemorrhoids, may lead to inflammation of the portal vein (pyelphlebitis) . . ." "Peptic ulcer . . . is probably always an infarct."

Page 109. ". . . diseases of the skull bones (otitis) . . ."

Page 161. "The tumors composed of nerve tissue are rare."

Page 187. "Some patients prefer not to disclose their identity and the pseudonym of John Doe is most popular in these instances. It is probably advisable not to express any signs of having heard this name before."

Two further objections are to be added. One is the character of the illustrations. One of them, for instance, was taken from Billroth and most of the others might accompany a book written a hundred years ago but certainly are not worthy of modern publications. The other objection is the fact that an attempt has been made to instruct the nurses in regard to clinical pathologic procedures. Not only is the instruction inadequate, but in some instances it is not correct.

Problems of Nervous Anatomy. By J. Boeke, LL.D., Professor of Histology and Embryology, the University of Utrecht, Utrecht. Cloth. Price, \$2.75. Pp. 161, with 48 illustrations. New York & London: Oxford University Press, 1940.

This little book contains the substance of three lectures delivered at the Universities of London and Oxford in 1937 and of a lecture delivered before the Anatomische Gesellschaft the same year. The book is divided into four chapters corresponding to these four lectures and dealing with (1) changes in the spinal and sympathetic innervation of the skin during degeneration and regeneration, (2) the sympathetic ground plexus in the glands, muscles and connective tissues of the body, (3) the problem of the "interstitial cells" in the sympathetic nervous system: their relation to neurons, and the innervation impulse as a humoral change in the tissues, and (4) the present state of the neuron doctrine and our knowledge of the synaptic junctions between the nerve cells themselves and between nerve cells and end organs. The second and third chapters contain a clear statement of the author's conception of the connections between the sympathetic nerve fibers and the innervated tissues, i. e. the glands, smooth muscles and, strangely enough, also connective

tissue. This connection consists of a continuous unbroken net of very "delicate interwoven and anastomosing nonmyelinated nerve fibers, running in strands or flattened bands of extremely delicate neurofibrillae with scattered nuclei, forming the terminations of the sympathetic plexuses" and including many "interstitial" cells. These interstitial cells, which many authors have regarded as connective tissue elements, are interpreted as nerve cells. Since the individual nerve fibers of the sympathetic nerves are thought to lose themselves in this diffuse network, the individual sympathetic neurons are diffusely connected at the periphery. Boeke accepts without question the conception of a humoral transmission of nerve impulses and he believes that the diffuse terminal net which he describes is especially adapted to this mode of transmission. The concluding chapter contains a not very illuminating argument against the validity of the neuron theory. The illustrations are excellent and present very well the conception of the terminal net. They are all interpretative drawings and as such lack the objectivity of photomicrographs. The book is a valuable contribution to a controversial subject but is to be taken as an expression of the author's personal convictions rather than as presenting a final solution of the problems discussed.

Textbook of Biochemistry. By Benjamin Harrow, Ph.D., Professor of Chemistry, City College, College of the City of New York. Second edition. Cloth. Price, \$3.75. Pp. 439, with 88 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

One would expect that the new edition of Harrow's textbook should prove to be popular for a first course in biochemistry and for medical or dental students. Indeed, most medical practitioners will find it a valuable book for a succinct review of biochemistry. It is clearly and simply written, presupposes little knowledge of biochemistry on the part of the reader, and adequately presents the main outlines of the subject. The author first considers the chemistry of carbohydrates, fats, proteins, nucleoproteins and enzymes. He then discusses the subjects of foods and vitamins and of syntheses in the plant kingdom. This leads logically to a consideration of digestion and absorption by the animal body and the mechanism of metabolism and excretion of foodstuffs. Obviously, in a book intended to serve as a textbook it is impossible to cover in great detail the tremendous advances which have been made in biochemistry in the last two decades. Nevertheless Dr. Harrow has succeeded in incorporating wherever possible the most modern developments and interpretations. This is clearly illustrated in the chapters on vitamins and hormones. An excellent practice has been followed in the choice of references for the various chapters. Individual papers have been selected with a view to training the student in the experimental method of approach. The emphasis in the bibliography has been placed on critical, modern reviews. The book contains numerous well chosen illustrations and a five page appendix on the nutritive value of foods.

La correction des téguments et des formes. Par le Professeur Pierre Sebillan. Paper. Price, 33 francs. Paris: Masson & Co, 1939.

This work encompasses a thorough but unpadding review of the entire field of plastic surgery. All phases of reconstruction are discussed in an engaging manner. The author is well known in France as an authority on the subject. Deformities of the face, including the nose, lips, jaws and ear, are thoroughly discussed and effectively illustrated by photographs and line drawings. There are also chapters on harelip, cleft palate, and so on. The author gained a great deal of experience in this type of work under Morestin, Sebillan and others during and after the war of 1914-1918. The world conflict demanded competence in reparative surgery for facial injuries, and it seems that recent events hold up in bold relief the necessity of possessing knowledge for effective reconstruction work on the face. The book opens with a discussion of generalities. The author stresses prompt emergency esthetic surgery, pointing out that many bad results follow neglect of proper primary care of wounds. The operative procedures described are pretty well standardized; the author describes those which in his hands have proved most effective. He uses by preference cartilage instead of bone transplants in operations about the nose. The bibliography following each chapter is a valuable addition to the work, ena-

bling the reader interested in any particular phase of the subject to familiarize himself with contemporary writings on the subject. All in all, the work is a well rounded out volume and can be recommended to all who are interested in the subject and who are conversant with the French language.

Elmer and Rose Physical Diagnosis. Revised by Harry Walker, M.D., F.A.C.P., Associate Professor of Medicine, Medical College of Virginia, Richmond, Va. Eighth edition. Cloth. Price, \$8.75. Pp. 792, with 293 illustrations. St. Louis: C. V. Mosby Company, 1940.

This volume is a new edition of the popular book on physical diagnosis by Elmer and Rose reedited by Dr. Harry Walker. The author states in the introduction to this edition that the book is to be a guide to students of medicine and to general medical practitioners. The author is one who has had considerable experience in teaching and in the practice of medicine, and he therefore can speak from knowledge gained by his own personal efforts. The book covers the entire problem of the bedside approach to clinical medicine from the standpoint of physical diagnosis and, in addition, there is incorporated in it quite a comprehensive bit of information concerning special procedure. The impression is that the author has used keen discrimination in his effort to evaluate the importance of both physical methods and the so-called procedures of precision. The first section of the book is taken up with the art of physical diagnosis and the physical changes which result in a modification of normal physical phenomena. The second section deals with special diseases and their important physical signs. The section which deals with physical diagnosis in neuropsychiatric patients is a distinct disappointment. This was not written by the author, and hence he is not responsible for the careless construction and numerous loose statements. This chapter should certainly be rewritten in the next edition and a large mass of uncertain and doubtful data eliminated. As a whole, the book is a commendable one and should have the justifiable support of those who find a book of this type obligatory in clinical medicine.

Diseases of the Nervous System. By W. Russell Brain, M.A., D.M., F.R.C.P., Physician with Charge of Out-Patients to the London Hospital, London. Second edition. Cloth. Price, \$9.25; 30s. Pp. 950, with 77 illustrations. New York & London: Oxford University Press, 1940.

A second edition of this useful compendium is welcome. Its compact lucid accounts of neurologic disorders are attractive and useful to students. The latest advances in neurologic knowledge have been included as far as they seem well established. In addition a useful new chapter has been added on the psychologic manifestations of organic nervous disease. In order to make room for this chapter without enlarging the book, the author has wisely omitted a discussion of endocrine disorders. Some new illustrations appear but, as in the first edition, seem to have been inserted haphazardly and add little to the book. The discussion of the neuroses might well have been omitted; not only is it too brief to be of any value but this subject is now adequately discussed in every psychiatric textbook. But only twenty-four pages of this book are occupied by the neuroses, so that this is not a serious defect. The discussions of neurophysiology and neuropathology are inadequate but, since these subjects are well presented in most American medical schools, this manual is quite satisfactory as a clinical guide.

Physiology and Anatomy. By Esther M. Grelshelmer, B.S. in Education, M.A., M.D., Professor of Physiology, Woman's Medical College of Pennsylvania, Philadelphia. Fourth edition. Cloth. Price, \$3.50. Pp. 822, with 474 illustrations. Philadelphia, Montreal & London: J. P. Lippincott Company, 1940.

This edition is thoroughly revised and reset to meet the most recent trends in teaching the subject. The subject matter has been arranged on the unit plan and consists of five units: the body as an integrated whole, the erect and moving body, integration and control of the body by the nervous system, maintaining the metabolism of the body and the reproductive system. The teacher's manual for use with the text is written by Miss Ostlie and prefaces each unit. The manual consists of thirty-six lectures and laboratory demonstrations which are most practical for the instruction of the student. In spite of the fact that the book is devoted to two subjects there is a definite text separation of them and the book can be used for separate courses in anatomy and physiology. The organization is excellent. The

written material is enhanced by helpful illustrations and each chapter is practically crystallized by summaries; some chapters contain a concise discussion of the application of the didactic material to clinical conditions. The material is presented in a terse and logical manner. It is explicit and graphic and is carefully edited. The illustrations are carefully selected and well done. The book is current and authoritative and is written in a lucid and engaging style. It should find popular acceptance among teachers of physical education and nurses. Its use is, however, not limited to these groups. Because of its simplicity in presentation it could profitably serve other groups of students who are interested in the study of human anatomy and physiology.

A Textbook of Physiology. By William H. Howell, Ph.D., M.D., ScD. Fourteenth edition. Cloth. Price, \$7.50. Pp. 1,117, with 330 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

The author again has brought his book down to date. His guiding principles have been the importance of simplicity and clearness in presenting facts and theories, and the need of limitation of material that must be selected from a bewildering number of researches that have been published in physiology and the related sciences. Amid the conflicting results of this mass of literature, the best that an author can do is to give as clear a picture as possible of the tendencies of the time. There are numerous illustrations, a few of which are beautifully reproduced in color; and yet it seems that the book would be more valuable to students had there been a still larger number of carefully selected illustrations.

Atlas der Hals-, Nasen-, Ohrenkrankheiten: Eine Sammlung typischer Krankheitsbilder mit topographischen, diagnostischen und therapeutischen Hinweisen. Von Dr. Carl von Elcken, ord. Professor an der Universität Berlin, und Dr. A. Schulz van Treeck, Assistent der Universitäts-Hals-, Nasen-, Ohrenklinik der Charité, Berlin. Cloth. Price, 32 marks. Pp. 199, with 461 illustrations. Leipzig: Georg Thieme, 1940.

This fine work cannot be too highly praised. It is a magnificent tribute to the otolaryngologic, not to mention the publisher's, art. The portion devoted to text is minimal. For the larger part this atlas depicts familiar conditions in the ear, nose and throat. Less commonly seen situations are by no means neglected, however. The larger number of reproductions of disease conditions are in color so masterfully executed that the pleasure derived in gazing at them almost equals the informative aspect. In the section devoted to otology alone the illustrations number over 125, and similarly those relating to the nose, larynx and pharynx are generously apportioned. Intended chiefly for students and general practitioners, this work is nevertheless of great value to the specialist. Besides the disease conditions so beautifully portrayed there are adequate sections relating to topographic anatomy and therapeutic interventions.

The Public Health Nurse and Her Patient. By Ruth Gilbert, Supervisor of Social Work, Psychiatric Service in the Community, New Haven. Cloth. Price, \$2.25. Pp. 396. New York: Commonwealth Fund; London: Oxford University Press, 1940.

This book is of interest primarily to nurses engaged in public health nursing. It is a study of the nurse's mental attitude and the philosophy of her work as it involves her relationship with patients, other nurses and co-workers. Originally entitled "Mental Hygiene in Public Health Nursing," it deals with situations which confront the nurse in her work. It contains chapters on nurses' attitudes, patients' attitudes, physical defects and injuries, mental defects and disease, the building of relationships, the nurse and her group, the nurse and the maternity patient, the child in his family and nursing problems related thereto, and familiar training situations relating to the training of the infant. A chapter is devoted to interagency relationships. Except for casual references there is no adequate discussion of the relationship of the public health nurse to the practicing physician, although this constitutes one of the most important and frequently disastrous relationships, especially with inadequately trained nurses working under insufficient supervision. The term "physician" and its equivalent "doctor" do not appear in the index, nor are medical relationships indexed under that heading.

Except for this inadequacy, the book should be extremely useful to the public health nurse and not without value to the

private duty nurse, since patients are patients regardless of the label which may be affixed to the nurse who is serving them. Unlike much professionally self-conscious literature, this book is not a bore but is distinctly readable. Like all publications of the Commonwealth Fund, it is beautifully printed and bound.

A Manual of Otolaryngology, Rhinology and Laryngology. By Howard Charles Ballenger, M.D., F.A.C.S., Assistant Professor of Otolaryngology, Northwestern University School of Medicine, Chicago. Cloth. Price, \$3.75. Pp. 302, with 94 illustrations. Philadelphia: Lea & Febiger, 1940.

The author has endeavored to produce a textbook chiefly for the use of undergraduate students. Such a work needs to be made concise, and in the effort to be brief arise all the possibilities for errors in judgment as to what to and what not to retain. The ideal textbook for students would abound in numerous illustrations of anatomic, histologic and pathologic importance. Their number would of necessity reduce their size and so for clarity's sake they ought to be in large part semidiagrammatic. Most of the illustrations have a familiar appearance. They appear to come from the author's larger and much older work, and it is a pity that an entirely new set was not prepared. In most other respects the author has done well. His clinical judgment is distinguished by good sense, he is not an enthusiast for indiscriminate surgical intervention and he is familiar with important recent advances in the physiology of his field.

Standardized Tests and Educational Practice. By Ellsha F. Bliss Jr. Paper. Price, 75 cents. Pp. 29. Brooklyn, N. Y.: The Author, 1940.

This pamphlet seems to express a deep-seated and intense, but rather vague, resentment and dissatisfaction with the existing methods by which intelligence, aptitude and other psychologic tests are employed in the schools. An ordinance is proposed by means of which the purchase, preparation, administration and interpretation of such tests could supposedly be regulated, although the pamphlet also condemns what it calls political regulation while recommending an ordinance to be adopted by local political bodies, plus federal regulation. The text of the ordinance and the involved cumbersome style in which the pamphlet is written make it extremely difficult to interpret. There is, in fact, no assurance that the central idea, if any, contained in this pamphlet is not so deeply buried in words that it is not totally incomprehensible.

Insurance of the Expense of Medical Service. By Wendell A. Millman. [Reprinted from the Transactions of the Actuarial Society of America, Vol. XLII, Part I, No. 103, May 1940]. Paper. Pp. 114-149. New York, 1940.

This pamphlet is almost the only attempt to apply actuarial calculations to the problem of insurance of the expense of medical service. The peculiar effect on actuarial calculations of the relations between medical service needed and medical service sought under the influence of insurance is noted, as is also the analogous difficulty of exercising professional control over the amount and quality of service given. Practically all the worthwhile studies of costs of medical care and income of physicians are utilized and several insurance schemes are discussed. Elements in medical service which are insurable are analyzed and some of the methods of control of the more hazardous elements are discussed.

Le syndrome de désintégration phonétique dans l'aphasie. Par Th. Alajouanine, professeur agrégé à la Faculté de médecine de Paris, André Ombredane, directeur-adjoint du laboratoire de psycho-biologie de l'enfant à l'Ecole pratique des hautes-études, et Marguerite Durand, assistante à l'Institut de phonétique. Paper. Price, 80 cents. Pp. 138, with 44 illustrations. Paris: Masson & Cie, 1939.

The authors have made a careful study of the disturbances of speech in the aphasic. For their phonetic studies they have used graphic registration of the sound waves and describe in detail the variations from normal. This is an interesting study of the peripheral manifestations of a central speech disorder.

Allergy. By Leo H. Crip, M.D., Consultant, Veterans' Administration, Pittsburgh. In collaboration with the Division of Post Graduate Instruction and Medical Research, Medical and Hospital Service, Veterans' Administration. Veterans' Administration Medical and Hospital Service, Clinical Bulletin No. 29. Paper. Price, 10 cents. Pp. 60. Washington, D. C.: Supl. of Doc., Government Printing Office, 1940.

This is a brief discussion of the present status of knowledge of anaphylaxis and allergy in man. As an introduction to the subject it should be useful. Its scope is rather limited.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Compensability of Death from Lobar Pneumonia.—The workmen's compensation act of North Dakota provides: "The term 'injury' includes in addition to any injury by accident, any disease proximately caused by the employment." Tweten, an employee of Wells County, N. D., contracted lobar pneumonia following a soaking received while performing outside work on the fair grounds during cold and rainy weather. He died as the result of the pneumonia. His wife, the claimant, filed a claim for compensation under the workmen's compensation act of North Dakota. Her claim was rejected by the North Dakota workmen's compensation bureau. This ruling was reversed by the district court, Wells County, N. D., and judgment was rendered for the claimant. On appeal to the Supreme Court of North Dakota the judgment for the claimant was affirmed and the workmen's compensation bureau petitioned that court for a rehearing.

The medical testimony, said the Supreme Court, was in accord that exposure to cold and inclement weather frequently is a contributing cause of pneumonia. In the judgment of the court there was no question but that the deceased died from lobar pneumonia contracted as a result of exposure to inclement weather in the course of his employment. The court could not agree with the workmen's compensation bureau's contention that the disease from which Tweten died was not a compensable "injury" within the meaning of the workmen's compensation act of North Dakota. The court pointed out that a Texas case, *Amann v. Republic Underwriters*, 100 S. W. (2d) 778, on which the bureau relied and which denied compensation under circumstances similar to those in the instant case, was decided under the Texas workmen's compensation act, which differs from the North Dakota act and defines a compensable injury to be "damage or harm to the physical structure of the body and such diseases or infection as naturally result therefrom." The language in the Texas act makes compensable only such diseases as are caused by a prior physical injury rather than by a particular employment. Under the North Dakota act, however, even prior to the enactment of the 1925 amendment quoted above, a physical impact was not a necessary prerequisite to a compensable "injury." In the opinion of the court the 1925 amendment merely enlarged the meaning of the term "injury" and included within its meaning any disease proximately caused by the employment. The court concluded, therefore, that to be compensable a disease need not arise from, or be directly traceable to, some physical impact or hurt, and so it held that Tweten's death from pneumonia was compensable. Accordingly, the petition for a rehearing was denied and the judgment for the claimant was upheld.—*Tweten v. North Dakota Workmen's Compensation Bureau (N. D.)*, 287 N. W. 304.

Medical Practice Acts: Right of Physician and Corporate Employer to Enjoin Board of Examiners from Revoking Physician's License.—Fisch, a physician licensed to practice in Minnesota, agreed with an incorporated social and fraternal organization to render medical services to members of the organization and to their families. Apparently, Fisch was paid directly by the organization, but whether on a monthly salary or on a fee basis the reported decision does not state. Without the payment of additional charges other than their membership fees in the organization, members of the organization and their families were entitled to medical services from Fisch. Fisch and the fraternal organization sought to enjoin the board of medical examiners of Minnesota from instituting proceedings to revoke Fisch's license to practice in Minnesota, based on the theory that Fisch was guilty of unprofessional conduct because of his connection with the corporation. The plaintiffs alleged that the threatened action of the board would

be an interference with the contractual relationship existing between them. The trial court dismissed the action and the plaintiffs appealed to the Supreme Court of Minnesota.

It is apparent, said the Supreme Court, that what the plaintiffs really seek by this action is a judicial determination that the contract between them is a valid one; in other words, what they actually seek is the equivalent of a declaratory judgment. Since the board of medical examiners is a body organized and existing by virtue of legislative enactment, courts must exercise extreme caution in passing on its actions, especially if what the board proposes to do and what the plaintiffs want enjoined lies within the jurisdictional authority of the board. Unquestionably, the Minnesota medical practice act authorizes the board to "suspend or revoke the license of, any person guilty of immoral, dishonorable, or unprofessional conduct, but subject to the right of the applicant or licentiate to appeal to the district court in the proper county on the questions of law and fact." (3 Mason Minn. St. 1940 Supp., Sec. 5707.) As to what constitutes "immoral, dishonorable, or unprofessional conduct" the statute affords adequate definitions. As to Fisch, the sole question is whether or not he has an adequate remedy at law under the section just referred to. If he has, then courts have no right to interfere except as provided by the law presented, i. e., to review on appeal "the questions of law and fact." The board has jurisdiction to proceed against any member of the medical profession, and adequate means are afforded on hearings held by the board for the accused physician to make any showing material to the issues made on any charge brought against him. Review from the board's decision is provided, hence the legal remedy is there and obviously is ample. As to the physician, therefore, in the judgment of the court the trial court clearly was right in dismissing the suit.

As to the corporate plaintiff, the fraternal organization, continued the court, it is apparent that its sole desire is to enjoin the board from proceeding against its physician employee. It has no license or right of its own of or concerning which the board has any jurisdiction. It cannot "interfere" with any proceedings that may be brought by the board against the physician employee. By joining their forces the plaintiffs cannot add one whit to their alleged cause. If that could be done, the board in practically every case would be handicapped and perhaps prevented from proceeding against any practitioner, since even a quack would be likely to get some one to join him in an injunction suit.

The Supreme Court accordingly confirmed the order of the trial court dismissing the suit.—*Fisch v. Sivertsen et al., Comprising State Board of Medical Examiners (Minn.)*, 292 N. W. 758.

- Southern Surgical Association, Hot Springs, Va., Dec. 10-12. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Surgical Association, Topeka, Kan., Dec. 6-7. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Acute Ulcerative Esophagitis.—Bloch discusses twenty-six cases of acute ulcerative esophagitis found at necropsy. Twenty of the cases were in adults and six in infants. In infants the condition may be due to thrush or to a complication of a congenital lesion, such as esophageal narrowing. The ages of the adults were between the third and the eighth decades; six of the patients were in the seventies. Six were men and fourteen women. Fourteen had been operated on, ten for disorders of the gastrointestinal tract. Of the non-surgical patients two died of acute coronary occlusion, one of congestive heart failure and hypertension, one of granulocytopenia with acute tracheobronchitis, one of carcinoma of the pancreas with duodenal invasion and one of subphrenic abscess and gastric ulcer complicating prostatic disease. The frequent association of peptic ulcer with acute ulcerative esophagitis has been observed by other workers. Little is known about the etiology of acute esophagitis. Butt and Vinson believe that the trauma produced by an indwelling Levin tube for decompressing the abdomen or irritation from vomiting are important causes. Intubation was done in eleven of seventeen cases of the present series in which operation was performed. Seven vomited and five, after intubation, vomited. It is not unreasonable to accept vomiting and intubation as a causative factor in the production of acute esophagitis. However, vomiting is extremely common postoperatively but acute esophagitis is comparatively rare. Penner and Bernheim believe that the same cause, the mechanism of shock, is responsible for the production of postoperative acute esophagitis, gastritis, duodenitis and colitis. In the present series at least

eleven patients who were operated on suffered from what might well be considered shock. One of the patients, following a gastric resection, showed not only acute esophagitis but acute membranous gastritis, duodenitis and colitis. Again many patients died of shock, but acute esophagitis did not develop in them. Other etiologic factors undoubtedly play a part. Embolism and thrombosis are favored by the presence of large venous channels in the lower end of the esophagus. The nervous system also must be considered. One of Bloch's patients had syphilitic meningo-encephalitis, another acromegaly and a third acute fulminating encephalitis. In contrast to chronic esophagitis there seems to be no way of diagnosing the acute type. Vomiting or regurgitation of blood stained fluid or the obtaining of such fluid through a tube should arouse the suspicion of its presence. Here the question arises whether vomiting is a symptom of or the cause of the esophagitis. Unfortunately, when acute esophagitis is present the underlying and primary condition is extremely serious. There is no special form of therapy for this type of case.

Secretin Test for Pancreatic Diseases.—Diamond and Siegel performed 130 secretin tests on 104 individuals; twenty-four were normal subjects and included physicians, students and others with unrelated ailments, and eighty were patients having such conditions as cholelithiasis, pancreatitis, obstructive jaundice, pancreatic cysts, steatorrhea, diabetes, hepatic cirrhosis with syphilis and ulcerative colitis. The test supplied the authors with valuable information of disturbed function of the gland in chronic states that had been unrecognized and unsuspected. In cholelithiasis with common duct stones the pancreas became simultaneously affected, revealing various degrees of disturbed function. In obstructive lesions when the pancreatic duct is encroached on from growths in the proximity of the duct the test supplied diagnostic data through a diminished or totally absent response, depending on the extent of blockage of the duct. In syphilis the test seemed to show a depressed function of the pancreas. This likewise occurred in cirrhosis of the liver, chronic alcoholism, acute yellow atrophy of the liver and the graver forms of toxic hepatitis. In the steatorrheas the test was most valuable in indicating the presence of pancreatic deficiencies and helped to differentiate between the idiopathic group including sprue and those with pancreatic lesions. In follow-up studies of the steatorrhea group the test showed the reversibility of the function and was consistent with the clinical improvement of the patient, indicating the degree of recovery.

Puerperal Infection.—Watson summarizes the advances in knowledge gained about puerperal infection in the last twenty years as follows: 1. Recognition of the part played by the anaerobes in puerperal and postabortal infection. 2. Proof that these anaerobic infections are endogenous in origin. 3. Proof that shock, hemorrhage, prolonged labor and traumatization of tissue predisposes to such infections. 4. Realization that the removal of dead and decomposing material resulting from this type of infection can, in most instances, be effected with no

risk, and usually with great benefit to the patient. 5. Identification of the different groups of the beta hemolytic streptococcus and proof that only group A is virulent in the human subject. 6. Establishment of the fact that infection with this organism is practically always exogenous. 7. Proof that these organisms are usually conveyed to the patient by a carrier who harbors them in the mouth, nose or throat. 8. Demonstration of the fact that the risk of infecting patients is practically nil by periodic nose and throat culture of all the members of the obstetric staff and of carriers, and complete masking of the nose and mouth of those attending the parturient and puerperal woman. 9. Demonstration of the persistence for long periods of the organisms in the environment of an infected individual even after she is removed from it. 10. A recognition of the necessity for complete isolation of all such infected women. 11. The discovery of the beneficial effects of sulfanilamide and its derivatives in streptococcal, gonococcal and *Bacillus coli* infections.

Androgenic Therapy in Gynecologic Practice.—Huffman reviews the experimental work and the clinical results obtained with androgen therapy in gynecology and states that the effects among twenty-two women who received androgenic therapy parallel those produced in laboratory animals by injections of testosterone propionate. Functional uterine bleeding was inhibited by the preparation. No notable masculinizing changes developed, except occasional temporary hypertrophy of the clitoris. Three patients have been under observation for more than two years. Testosterone propionate caused genital activity to cease in human beings as it has in the adult female rabbits and rats. This effect is the result of pituitary rather than ovarian inactivation. The changes produced are temporary, and the cyclic phenomena of the genitalia are resumed after administration of the drug is continued. When from 350 to 500 mg. of testosterone propionate is injected over a considerable period of time, temporary masculinizing changes, especially hypertrophy of the clitoris, may appear. Inhibition of lactation after testosterone propionate therapy has been observed clinically and microscopically in animals. According to the literature, reproduction is possible and normal children have been born to women who have been treated with the preparation prior to their pregnancies. There is considerable evidence to suggest that androgenic therapy has a place in the treatment of functional uterine bleeding, mastalgias, puerperal breast engorgement and inhibition of lactation. Further investigation of its use in dysmenorrhea and menstrual molimina is indicated. The use of the preparation may perhaps be advantageous in preference to the estrogens in certain menopausal disturbances.

Peripheral Arterial Embolism.—Koucky and his associates attempted to evaluate therapeutic measures in twenty-five cases of peripheral arterial embolism treated at the Cook County Hospital from 1928 to 1938. This probably does not represent all the cases, as many may have been filed under other diagnoses, remained unrecognized or cured spontaneously through the establishment of collateral circulation. Most cases of peripheral arterial embolism occur in late adult life. Two of the twenty-five patients were less than 10 years of age and two were between 70 and 80 years. As is usually observed, mitral heart disease, on the basis of subacute bacterial or chronic rheumatic carditis, was the direct etiologic agent. The lower extremities were more frequently involved than the upper. In the present series the ratio was 5:20. The treatment of arterial embolism is divided into four types: nonoperative, arteriotomy, arterectomy and amputation. An embolism to the upper extremity can usually be treated conservatively because the collateral circulation will furnish sufficient blood to the limb. Embolism of any large vessel in the lower extremity down to and including the popliteal arteries is a surgical emergency and should be treated as such without any hopeful procrastination. The time factor in the performance of an embolectomy is of great importance and one should not wait once the site of the embolus is reasonably certain. With procrastination, reformation of a thrombus at the site at which the embolus has impinged becomes an added risk to embolectomy. If a free flow of blood after the embolus is removed is impossible, it is best to remove a segment of the artery (arterectomy), thus removing the irritable focus of the vasospastic reflex and facilitating collateral circulation. From a review of the cases the authors have learned that the usual case follows a more or less typical course toward a fatal termination and that this course can be altered. The patient is brought to the hospital in poor general condition, conservative methods are employed, and he seems to rally and appears in a much better condition. Meanwhile the extremity becomes gangrenous. As

the patient improves he is kept on this conservative management for days or even weeks, appearing constantly to improve. Then there is a general increase in the toxemia. The fever rises, the pulse accelerates and a moderate leukocytosis gives evidence of toxemia. As this increases, the emergency guillotine amputation is performed. This is followed by shock, infection and death. The authors found that in cases in which amputation was done as soon as improvement was apparent the results were better. These amputations were far better borne and could be carried out as planned, elective procedures. The average duration of life of three patients following embolectomy was thirty-nine hours, of four of the six following amputation forty-seven days, and of fourteen of the sixteen given conservative treatment twenty days, a respective mortality rate of 100, 66 and 88 per cent.

Alcohol for Suppurative Generalized Peritonitis.—Behan and his co-workers have used since 1930 in all cases of peritonitis at operation intraperitoneal lavage with 70 per cent ethyl alcohol as a routine. If free fibrinous fluid or pus was found in the peritoneal cavity, a culture was taken and this was immediately followed by the introduction of from 100 to 200 cc. or more of 70 per cent ethyl alcohol into the abdominal cavity. The amount may be increased so that the walled off and localized abscess cavity is filled or, if a generalized peritonitis is present, so that the free peritoneal cavity is flooded. In generalized suppurative peritonitis the abdominal wall is elevated by retractors on either side of the incision and sufficient alcohol is introduced to fill the peritoneal cavity so that the fluid level is even with the margin of the incision. The alcohol remains in situ for a few minutes and is then siphoned off by suction. The usual complications of suppurative peritonitis (gastromesenteric ileus, paralytic ileus, tympany, persistent vomiting and hiccups) seldom occurred when this therapy was used. The authors believe the beneficial effect of alcohol due to its bactericidal action, reduction of bacterial activity, increase of resistance of all the tissues during this period, decreased absorption of toxins and poisonous tissue products during the period of reduced bacterial activity, induced hyperemia in the surface layers of the peritoneum and the beneficial systemic effect of the counter action of toxic products (because of inhibited absorption) in the circulation. The absorbed alcohol may act as a mild blood antiseptic and be a source of energy for the destruction of foreign proteins and other toxic substances, and it may also be of nutrient value because of its high caloric content. Forty-three cases of localized and forty-nine cases of generalized suppurative peritonitis were studied. Forty-six cases were treated by the alcoholic lavage of the abdominal cavity and the rest by wide incision and removal, if possible, of the diseased appendix. The majority of cases of acute suppurative appendicitis, localized appendical abscess and generalized suppurative peritonitis occurred in patients between 10 and 30 years of age. The average time of operation was about 4.23 days after the onset of the acute symptoms. The average period of delay before operation in cases in which alcohol lavage was used was 4.77 days and in the others 3.69 days. Patients treated with intra-abdominal alcohol lavage recovered more quickly than did those for whom alcohol was not used. In the alcohol treated group the temperature dropped to normal on an average, 9.1 days after operation, with the shortest period three days and the longest forty days (the latter case was complicated by postoperative intestinal obstruction). The average in the cases not treated with alcohol was 12.48 days. The shortest time in which the temperature returned to normal in this series was three days, the longest fifty-nine days. The pulse rate rose postoperatively to an average of 112 in the alcohol treated cases and to 127 in the other series. This may indicate that patients treated with alcohol did not remain so toxic. The average hospital time of the patients treated with alcohol was 22.04 days as compared to 27.59 days for those not so treated. The death rate in the series of generalized peritonitis treated with alcohol was 8.69 as compared to 45.39 per cent in the cases not treated with alcohol. The deaths were due to complications. There were no deaths among the cases of localized peritonitis. The prognosis was much better when culture of the intra-abdominal exudate showed a pure strain of organism than when it presented more than one organism.

- Tuberculosis in Rabbits: Further Comparison of Roentgenologic and Pathologic Findings in Primary and Reinfection Experimental Pulmonary Tuberculosis in Rabbits: II. Reinfection Tuberculosis. H. E. Burke, New York.—p. 499.

Twenty Years' Experience with Artificial Pneumothorax.—For Jennings and his associates artificial pneumothorax has been for the last twenty years, and still is, the first choice among the various procedures used to collapse the lung. The method has the following advantages: 1. When satisfactory, pneumothorax collapses the diseased areas better than other methods. 2. It prevents the formation of pleural adhesions. 3. It can be augmented by other measures. 4. It may be discontinued with relative ease. It can never be predicted whether or not pneumothorax can be satisfactorily induced; only a trial will ascertain this. The authors think that, if such a trial does not establish collapse, other procedures should be used. They review the records of all patients for whom pneumothorax was considered suitable and who were discharged from Glen Lake Sanatorium prior to January 1937. There were 1,027 patients for whom unilateral pneumothorax was done or considered suitable. Among these there were 249 (24.2 per cent) who could not be given injections of air. Only a portion of the pleural space of 346 patients was found free from adhesions and the amount of pulmonary collapse was not sufficient to affect either the symptoms or the lesions. There were 111 patients who received some benefit from the air introduced into the pleural space. Either their symptoms were decreased or their lesions were partly controlled. There were 321 patients whose condition was classed as satisfactory because both their symptoms and their lesions were completely controlled by pneumothorax. Thus satisfactory collapse was obtained for only one out of every three patients. Follow-up examinations from one to twenty years revealed that patients who had the most satisfactory collapse and who had the greatest amount of free pleural space were in the best condition. Of patients not benefited by pneumothorax and subjected to further collapse, one out of four was dead three years from the time the pneumothorax was originally induced. Of those who had no other collapse procedures three out of four were dead. Further collapse constituted phrenic nerve surgery for 160 patients and thoracoplasty for fifty-four, while 125 had both phrenic nerve excision and thoracoplasty and seven patients had a combination of various procedures. These two groups of patients were treated over the same period of time in the same institution. Among 432 patients benefited by pneumothorax there were forty-eight who had phrenic nerve excision and ten who had intrapleural pneumonolysis. Thirty patients had phrenic nerve excision and thoracoplasty. Sixteen patients had a combination of various types of surgical collapse. Twenty-seven had thoracoplasty alone. Bilateral pneumothorax was induced or attempted 144 times. Seventy-six, or 52.8 per cent, of the patients are living and sixty-eight, or 47.2 per cent, are dead. Fifty of the sixty-eight deaths occurred within the first three year period. Bilateral pneumothorax is indicated for patients with active bilateral tuberculosis, for patients who develop tuberculosis in the contralateral lung during unilateral pneumothorax treatment and for patients whose tuberculosis becomes activated in the contralateral lung. A considerable number of the patients with bilateral pneumothorax underwent further surgery. The authors conclude that pneumothorax offers the best method of collapse when tuberculous lesions can be satisfactorily controlled by it. It shortens the period of bed rest.

Instability of Tuberculin Reaction.—Until recently an impression prevailed that, once established, the tuberculin reaction remained positive indefinitely. Dahlstrom points out that frequent discovery of calcified nodules, presumably of tuberculous origin, in patients not reacting to tuberculin has recently raised the question whether tuberculin allergy may not disappear after complete healing of the lesion and whether the allergy demonstrable in many cases of calcified lesions may not be dependent on chance reinfection rather than on the persistence of the original allergy. The question arises whether the tuberculin reaction, once established, remains positive during the activity of the lesion responsible for the initiation of allergy, in other words whether the tuberculin reaction is always positive in the presence of active tuberculous lesions. This study was undertaken to answer these questions and, in the event that the tuberculin reaction proved to be unstable, to determine the conditions under which allergy was maintained or lost. The dispensary records of 3,919 members of 513 families under observation from five to fifteen years were examined. Of these 2,490 were positive to tuberculin on at least one examination and 276, or 11.1 per cent, passed from the positive to the negative state during the period of observation. The lower the original degree of sensitiveness the greater was the likelihood of reversal from positive to negative. Only 0.4 per cent of 1,090 people giving a 3 plus reaction to the standard first dose of tuberculin became tuberculin negative, whereas the negative state supervened in 70 per cent of 185 persons giving a 1 plus reaction to the second dose. The greater the degree of family exposure the more likely was the reaction to remain positive. In families with no history of tuberculosis in any member 24 per cent of the members became negative, whereas among sixty-three reactors in families in which a patient with positive sputum resided constantly only one person (1.6 per cent) became negative. The tuberculin reaction never became negative in the group under consideration in the presence of lesions of active reinfection type tuberculosis but became negative in a small number of cases of tuberculous lesions of the type diagnosed only by x-ray examination. Reactive capacity disappeared in 0.72 per cent of the total number of patients with recognizable tuberculous lesions. The overwhelming majority of the unstable reactors were children. Reversion to negative reaction proved rare in adult life.

Blood Preservation.—Scudder obtained refrigerated plasma samples of varying ages from three different blood banks in New York City, unrefrigerated samples from Salisbury, N. C., plasma from the necropsy room of the Presbyterian Hospital and placental plasma from the Sloane Hospital for Women.

To ascertain what effect the lyophile process has on serum proteins, a sample of dried serum was supplied by Ravdin from Philadelphia. The electrophoretic method of analysis of proteins reported by Longworth and MacInnes was used. After a comparison of the values for preserved plasma with the values for fresh plasma in his studies and those of others, Scudder points out that the greatest change appears in the decrease of albumin as well as a change in the components which constitute the albumin/globulin ratio. Fibrinogen appears unaltered. A definite increase appears in the gamma globulin. This decrease in albumin and the increase in gamma globulin have been observed by Knoll. Two specimens which had been kept in a specially designed bottle showed the least change. In comparing the refrigerated samples with those that had been kept at room temperature and had been shipped about the country, the greatest difference was seen in the beta globulin fraction, the beta globulin disturbance was absent and the beta globulin/albumin ratio was decreased. The necropsy serum and plasma were abnormal. The placental plasma appeared within normal limits. The lyophilized serum presented an anomaly in that the beta disturbance was missing. It appears that postmortem blood is abnormal; this may not apply to blood collected from those who have died suddenly. Placental blood appears to be a normal source for conserved blood. Lyophilized serum appears abnormal. Refrigeration seems to enhance the preservation of plasma as did the shape of the flask. Possibly denaturation of plasma proteins is slower under these conditions.

Plasma Loss in Dehydration and Shock.—Minot and Blalock discuss the two factors vasodilatation and loss of circulating volume which lead to a deficiency of intravascular fluid and the measures for preventing and treating secondary or hematogenic shock. Under normal conditions many factors cooperate to maintain a fluid balance between the tissue cells and the extracellular spaces and in the vascular system. The fluid intake and electrolyte must keep pace with their loss from the body. There must be sufficient plasma protein to attract and hold an adequate volume of fluid in the blood stream. The selective permeability of the capillaries allows water and crystalloids to pass freely but withholds most of the protein in the blood stream. Renal activity removes metabolic waste products and any excess of fluid or electrolytes taken into the body. A serious abnormality in any of these factors may result in disastrous changes in the amount and partition of body fluid. Among the simpler abnormal conditions which may lead to a serious reduction in the volume of circulating blood are severe dehydration and extensive hemorrhage. In addition to these an abnormal partition of body water may arise from a nutritional lack of adequate plasma protein, as occurs in nutritional edema. Hypoproteinemia on a nutritional basis does not often lead to serious circulatory failure, but it must be corrected as it is a likely factor in the development of postoperative complications and some instances of pulmonary edema and pneumonia. Frequently an abnormal partition in body water occurs because the capillaries have been injured, permitting plasma protein, water and crystalloids to pass through the capillary endothelium into the tissue spaces. Mechanical, chemical or thermal trauma and oxygen lack are common causes of increased permeability of the capillaries. Although details of hematogenic shock vary with the condition initiating it, the problem of treating impending hematogenic shock is to restore and maintain a more effective circulation in the presence of the operative abnormalities. Attempts to increase vasoconstriction with drugs has failed as a means of preventing shock. More promising results were obtained from the administration of adrenal cortex extract, but still a large part of the treatment must be replacement of the elements lost from the blood stream. The difficulty of fluid replacement therapy varies with the different conditions, but the patient's needs for fluid and electrolytes must be met. Blood plasma has been most efficacious for fluid replacement. The introduction of aqueous solutions dilutes the plasma colloids in the blood stream and, if already low, further dilution prevents the retention of the administered fluid in the blood stream. Tissue edema develops while the blood stream remains dehydrated. If extensive capillary damage exists, the continuous adminis-

tration of fluid by vein washes out more protein and as a result may actually reduce rather than increase the volume of circulating blood. The best guide as to the disposal being made of intravenously administered fluid is afforded by frequent measurements of hematocrit or hemoglobin and of plasma protein. The use of plasma rather than of whole blood avoids further burdening of the circulation with cellular elements which are already present in high concentration. Volume for volume, plasma transfusions introduce protein approximately twice as fast as whole blood and there is less danger of reactions. The disadvantages of plasma are the technical difficulties and time required for preparing it for transfusion and the larger amounts of blood which must be furnished by donors. Therefore the value and convenience of an available "plasma bank" is evident. However, lacking plasma, transfusions of whole blood should be administered promptly and repeatedly. Many attractions are offered by desiccated or lyophilized blood serum. The dried powder can be kept indefinitely and be dissolved in a small volume of water, giving a solution richer in protein than fresh plasma. When whole blood or plasma cannot be procured, the blood volume may be restored by intravenous injections of acacia solutions.

Gastric Acidity Before and After Operations.—Wangenstein and his collaborators state that the surgical staff, while still adhering to orthodox indications for operative intervention, varied the surgical procedure with the thought of garnering useful information concerning the role of various operations in the management of ulcer and the manner in which their influence is mediated. In addition, experimental procedures have been carried out on the dog in an attempt to assay further the validity of Edkins's hypothesis of pyloric and antral hormone control of the gastric phase of gastric secretion. The occurrence of gastrojejunal ulcer in two cases in which antral resection had been done because of continued bleeding from a duodenal ulcer suggested this study. In both cases a previous gastro-enterostomy had been done and, when antral resection was performed, no evidence of a gastrojejunal ulcer was observed. In both cases gastrojejunal ulcer followed antral excision within a few months. Sixty cases in which the following types of operative procedure were done were available for study: (group 1) twenty-nine cases of retrocolic gastrojejunostomy, (group 2) six of antral excision with complete terminolateral anastomosis (Pólya), (group 3) ten of extensive gastric resection including pylorus and antrum, (group 4) six of antral excision with extensive gastric resection (Finsterer's operation) accompanied by either partial (Hofmeister) or complete retrocolic terminolateral anastomosis (Pólya), (group 5) three of Schmilinsky's operation with provision for complete intragastric regurgitation for gastrojejunal ulcer following antral excision, (group 6) five of tubular excision (fundus and corpus) with gastrojejunostomy, leaving the antrum and pylorus intact and (group 7) three of tubular excision (fundus and corpus) without gastrojejunostomy, leaving the antrum and pylorus intact. The postoperative observations made in these cases include studies of gastric acidity, gastric emptying time (employing the neutralization test) and gastric evacuation time determined fluoroscopically after the patient swallowed 150 cc. of a thin barium sulfate mixture. The authors found that: 1. Extensive gastric resection by itself does not produce achlorhydria to maximal stimulation (histamine), even when combined with bilateral subdiaphragmatic vagotomy (group 7). 2. Extensive gastric resection, when combined with gastrojejunostomy providing opportunity for partial intragastric regurgitation of duodenal content, will usually produce achlorhydria to maximal stimulation (histamine). The lapse of time is an important factor in the development of such achlorhydria. 3. Excision of the antrum and pylorus (the small or partial gastric resection) fails to make the residual gastric segment achlorhydric to maximal stimulation. 4. Allowing the antrum and pylorus to remain, as is indicated particularly by group 6, does not militate against securing an achlorhydric stomach to maximal (histamine) stimulation, granted that an extensive gastric resection of the acid secreting area is performed. Group 4 will, in time, shed additional light on this issue. 5. Gastrojejunostomy is not

accompanied by achlorhydria to maximal stimulation. 6. The emptying time is decreased considerably in all anastomotic operations on the stomach (groups 1, 2, 3 and 4) and after extensive resection of the stomach without anastomosis (group 7). When the intragastric regurgitation of the duodenal content is complete, as it is in group 5, the emptying time is prolonged (barium sulfate evacuation time). On the basis of their observations the authors conclude that the Edkins hypothesis on the clinical side appears to be invalid. Proof of this lies in two occurrences: the consistent production of true achlorhydria in five cases in which there was duodenal ulcer after tubular resection of the corpus and fundus (attended by gastrojejunostomy), leaving the pylorus and antrum intact (group 6) and failure to produce true achlorhydria in cases of excision of the pylorus and antrum (group 2). On the experimental side their observations are still incomplete except that excision of the pylorus and antrum does not decrease the secretory capacity of fundic pouches. The importance of the acid factor in ulcer is emphasized by the occurrence of ulcers in cats after intragastric instillation of 0.4 per cent hydrochloride and after subcutaneous intramuscular implantation of histamine in beeswax.

Effect of Induced Thiamine Deficiency in Man.—

Williams and his associates confirm the observations of Williams, Mason and Smith by their own work, in which six subjects received a diet for eighty-eight days which provided less than 0.15 mg. of thiamine hydrochloride (50 international units of vitamin B₁) daily but which was otherwise adequate. After eleven days two of the subjects were given thiamine hydrochloride orally, without their knowledge, in gradually increasing daily doses. The four subjects who obtained no supplementary thiamine experienced striking evidences of nutritional deficiency. The two subjects whose diets were supplemented also showed evidences of deficiency until their total daily intake of the vitamin reached 0.95 mg. From then on they were free from symptoms and performed as effectively on a chest weight exercise machine as at the start of the study. With further increases of thiamine they improved still more, and when the daily intake reached 2 mg. they were strikingly more alert and attentive and their performance of the exercise was much more satisfactory than it had been originally. When the intake of thiamine was lowered by a return to the routine hospital diet, well-being, alertness and work performance again fell to the original level. This indicates that the institutional diet, which contained approximately from 0.6 to 0.8 mg. of thiamine hydrochloride daily, provided less than an optimal allowance. The food in this hospital compares favorably with that in most institutions and therefore institutional diets in general may be criticized on this score. The isolated withdrawal of thiamine from the diet did not produce beriberi. In the earlier study four subjects were given food that contained less than 0.15 mg. of thiamine daily for 147 days, and the four subjects of the present study received a diet that provided less than 0.15 mg. for eighty-eight days. Yet edema, cardiac dilatation and neuritic pain were absent in both groups. Mild tenderness of the muscles of the calves and paresthesia of the feet and legs and diminution of tendon reflexes were

observed. Pain to any degree was not present. The authors wonder whether thiamine is the vitamin the lack of which is responsible for the classic features of beriberi. They suggest that deficiency of the factors of the vitamin B complex other than thiamine may be more important in the production of such features than thiamine itself. The early stage of the condition induced by the restricted intake of thiamine closely resembled neurasthenia; the later stage simulated anorexia nervosa. The authors suggest that states of thiamine deficiency, as these exist in our part of the country, where few cases of beriberi or pellagra are encountered, should be looked for principally in cases rightly diagnosed as neurasthenia.

Necrobiosis Lipoidica Diabeticorum.—Hildebrand and her co-workers point out that since Oppenheim's description in 1929 of necrobiosis lipoidica diabeticorum seventy-eight cases have been reported, to which they add the eight encountered at the Mayo Clinic since 1936, when the first case was registered. In more than 87.2 per cent of all the cases diabetes mellitus has also been present, in a few instances the cutaneous lesions preceded the onset of diabetes by as long as eight years and among 10 per cent of patients with these lesions diabetes has not yet appeared. In those with diabetes the cutaneous lesions had developed from several months to as long as seventeen years after the onset of the diabetes. Aside from the high incidence of diabetes, study has failed to reveal the presence of any predominant associated disease which might have etiologic significance. All the patients were white and more than 80 per cent of them were women. The cutaneous lesions usually appeared when the patients were between 10 and 40 years of age, the average being 35 years. In the majority of the cases the diabetes has been poorly controlled throughout its course. Trauma seemed to play a definite part in the causation of the cutaneous condition, as from 12 to 16 per cent of the patients stated that bruises, cuts, scratches and mosquito bites preceded the necrobiosis. In approximately 85 per cent of all cases reported elsewhere and in 82 per cent of the authors' cases the lesions occurred on one or both legs below the knees. A diagnosis of necrobiosis lipoidica diabeticorum is possible on the clinical appearance of the lesions alone. The plaques are flattened with yellowish centers surrounded by violaceous or red-brown borders, with or without central ulceration. These lesions differ from other xanthomatoses, which are usually firm, yellowish papules occurring on the extensor surfaces of all four extremities. The intracellular deposit of lipoids in foam cells in the latter lesions makes recognition final. The pathogenesis of the condition remains obscure. Because of the vascular changes seen in the lesions, many authors have assumed that the disease is due to damage to the small blood vessels of the corium, possibly by circulating toxins, with subsequent thrombosis, necrosis and secondary imbibition of fat particles. Another hypothesis assumes a local lipid disturbance in the skin, based on a general disturbance in fat metabolism. Neither hypothesis has proved satisfactory. Treatment, either local or general, for most patients with diabetes mellitus has been of little avail. The cutaneous lesions typically run an indolent, chronic course, either slowly enlarging over a period of months or years or slowly receding to form depressed scars. Control of the glycosuria with proper diet and insulin seems to have little effect on them, although some authors have reported good results with diets low in fat. Three of the patients at the Mayo Clinic were placed on such a diet but no improvement occurred after they had been observed for from several months to a year. Local treatments, including injection of insulin at the site of the lesions, ultraviolet irradiation and various local medications, have been unsuccessful in accelerating healing.

Banti Syndrome.—According to Ravenna, accumulating evidence supports the view that Banti's splenomegaly is largely due to splenic congestion and that this congestion is not dependent on portal-venous obstruction. The congestion may be due to primary lesions of the small splenic arteries which regulate the blood flow into the spleen ("primary active congestion"). The human spleen should be considered an elastic rather than a contractile organ. Its variations in size depend on variations in the volume of inflowing blood rather than on

active contractions of the smooth muscle of its supporting framework. Mechanically the spleen might be defined as an automatic controller which regulates the pressure of the splenic venous blood in order to maintain the balance between the volume of inflowing blood and the amount which can be discharged through hepatic resistance. In pathologic conditions the splenic elasticity guarantees a pressure sufficient to secure the further progress of venous portal blood. Congestive splenic enlargement is therefore a mechanism to counterbalance either an increased volume of portal blood or an increased peripheral resistance to the discharge of a normal amount of blood. The Banti syndrome is a symptom complex dominated by chronic fibrocongestive splenomegaly, accompanied by portal hypertension and complicated by, or associated with, hepatic cirrhosis or thrombosis of the splenic and portal veins. It may depend on various determinable causative agents, either infective or toxic, or undeterminable ones. The splenic changes of the Banti syndrome are probably due to primary lesions of the splenic arterioles, the regulating power of which becomes insufficient to control the inflow of blood. The consequent congestive splenomegaly is the cause of the circulatory disturbance in the portal bed. Secondly, hepatic cirrhosis and venous thrombosis may aggravate the state of portal circulation.

Experimental Studies on Headache.—Ray and Wolff present data on the pain sensitive structures inside and outside the cranium obtained from 150 observations on thirty patients during operative procedures. The following conditions prevailed among the thirty patients: 1. Surgical exposure of cerebral lesions afforded an opportunity to make careful observations on the sensitivity to pain. 2. The patients were intelligent and cooperative, so that pain, its site and its nature could be determined. 3. The patients were relatively free of apprehension and of preoccupation with pain, requiring minimal analgesia. 4. The operative procedures were such that the patients were not prostrated or inarticulate and therefore could describe their sensations. 5. The stimulated structures were free of disease, insuring normal responses. Some of the "pain pathways" and mechanisms of headache after various stimuli were as follows: 1. The tissues covering the cranium are all more or less sensitive to pain, the arteries especially so. 2. Of the intracranial structures, the great venous sinuses and their tributaries from the surface of the brain, parts of the dura at the base, the dural arteries and the cerebral arteries at the base of the brain are sensitive to pain. 3. The cranium (including the diploic and emissary veins), the parenchyma, the dura, the pia-arachnoid, the ependymal lining of the ventricles and the choroid plexuses are not sensitive to pain. With the exception of sensations resulting from stimulation of the parenchyma and nerves, the only sensation of the intracranial structures was pain. Stimulation of the pain sensitive intracranial structures on or

above the superior surface of the tentorium cerebelli resulted in pain (pathways in the fifth cranial nerve) in various regions in front of a line drawn vertically from the ears across the top of the head; stimulation on or below the inferior surface resulted in pain behind this line. The pathways for this pain are chiefly in the ninth and tenth cranial and the upper three cervical nerves. From the data available, headache may result from (1) traction on the veins that pass to the venous sinuses from the surface of the brain and displacement of the great venous sinuses, (2) traction on the middle meningeal arteries, (3) traction on the large arteries at the base of the brain and their main branches, (4) distention and dilatation of intracranial and extracranial arteries, (5) inflammation in or about any of the pain sensitive structures of the head and (6) direct pressure by tumors on the cranial and cervical nerves. Intracranial diseases cause headache by involvement of more than one pain sensitive structure. Headache from intracranial disease is usually referred pain. Unilateral hyperalgesia localized in the parietal area may indicate a lesion near the middle meningeal artery, and hyperalgesia localized to the postauricular region a lesion about the internal auditory meatus.

Cancer of Tongue.—Martin and his associates studied the records of 556 consecutive patients with lingual cancer admitted to the Memorial Hospital during 1927 to 1934 inclusive. This series comprises all patients with microscopically proved lingual cancer except those observed for less than one month. At the Memorial Hospital lingual cancer comprises about 15 per cent of all tumors of the upper respiratory and alimentary tracts and about 25 per cent of all intra-oral tumors. The average age of the 556 patients was about 58 years at the time of admission; 87 per cent of the patients were men and 13 per cent were women. Chronic irritation was a predominating apparent etiologic factor in growths of the middle and anterior thirds of the tongue where precancerous changes, such as chronic diffuse or localized glossitis and leukoplakia, occur most often. At the base of the tongue, tissue changes as a result of chronic irritation are less definite. Such chronic irritation (leukoplakia, chronic glossitis and dental sepsis) are much more prevalent in men than in women, supporting the etiologic relationship of chronic irritation to intra-oral cancer. The chronicity of the irritant is more important than its nature. Single traumas probably have little effect. Routine Wassermann tests revealed that about 33 per cent of the patients had syphilis, in whom the immediate etiologic factor undoubtedly was the chronic glossitis of late syphilis. The influence of tobacco on lingual cancer is difficult to estimate; about 75 per cent of the male patients admitted moderate to heavy use of tobacco. This figure loses most of its significance, as even a higher percentage of the general adult male population uses tobacco. Only 9 per cent of the women admitted smoking. If only the nonsmokers of both sexes are considered, the disease is still more than twice as frequent in men as in women. In the sixth and seventh decades, when the incidence of intra-oral cancer is greatest, a large percentage of the general population has suffered dental diseases and defects for prolonged periods. However, their presence may be coincident with the "cancer age" rather than its direct cause. As with tobacco, dental factors render affirmation or denial impossible. Only 10 per cent of the patients had clean teeth in good repair. In clinic patients dental defects and sepsis were almost the rule. In a few instances the association of sharp, broken or worn teeth or ill fitting dentures with the growth is evident. The primary early small lesion was treated with radon seeds. Fractionated peroral roentgen irradiation supplemented by radon seeds was used for all except the small growths. Fractionated roentgen irradiation through the neck followed by supplementary radon seeds was used for cancer of the base of the tongue. Radon seeds ("overdosage") followed in from five to ten days by partial glossectomy was indicated for only a few bulky, fungating, partly necrotic tumors. The following variations were also employed: (1) roentgen irradiation for extremely radiosensitive tumors; supplementary interstitial irradiation being probably indicated in all cases, (2) low voltage, lightly filtered peroral roentgen irradiation for superficial growths on the anterior portion and dorsum of the tongue and (3) surgical

excision for fungating papillary tumors at the tip of the tongue. Complications following surgical procedures are apt to be acute and severe but of short duration; those following irradiation tend to be of lesser degree but of longer duration. Except in the earliest stages when the tumor is small and is situated on the edge of the anterior half of the tongue the prognosis of lingual cancer is bad. The average duration of life among the patients from the first symptom to death was twelve months, varying between two months and seven years when the immediate postoperative deaths are excluded. The five year end results of the 556 patients were as follows: Fifty-three patients without recurrence died of other causes. Five without recurrence were lost track of. Of the remaining 498, 368 died as a result of the cancer, two with a recurrence were lost track of and probably are dead, four are living with a recurrence of their cancer and 124 are free from lingual cancer five or more years after treatment. Thus a five year cure rate of 25 per cent obtains if the 124 successful results are divided by the determinate group of 498.

Ischemic Contracture of Lower Extremity.—Horwitz reports two cases of disabling deformities of the right lower extremity which persisted for eleven and fourteen years respectively. The two cases presented the following features: (1) healed fractures of the femur, (2) massive induration of the muscles of the leg and foot associated with atrophy and loss of motor power below the knee, (3) vascular dysfunction in the involved lower extremity, (4) contractural deformities of the foot and toes, (5) x-ray evidence of extra-osseous calcification of the leg and (6) histologic evidence in one case of massive degeneration of muscular tissue with fibrous tissue replacement and extensive calcification. In both cases the pathologic state in the lower extremity was identical with Volkmann's ischemic contracture. On the basis of his two cases and a review of eighteen cases reported in the literature the author concludes that such ischemic contracture must be anticipated after fracture or extensive injury to the soft tissues without fracture in the lower extremity, especially in the region of the knee and leg. The contracture and deformity may be avoided by fasciotomy during the acute (prodromal) stage. Deformities following contractures may be corrected by nonoperative and operative measures.

Acute Pancreatitis.—Lewison states that there were thirty-three cases of acute pancreatitis among 100,000 admissions between 1921 and 1939 to the Beth Israel Hospital. This incidence coincides with that reported by other investigators, but the author believes that its rarity may have been overestimated. Serum amylase and lipase studies indicate that acute pancreatitis may be mild and more prevalent than heretofore believed. In the milder form it may masquerade as biliary colic. The diagnosis of the thirty-three cases and two treated elsewhere was established or confirmed at operation. Cases of manifest chronic pancreatitis, acute pancreatitis secondary to primary processes elsewhere, acute pancreatitis resulting from perforation of a peptic ulcer and pancreatic calculi were not considered. The author points out that a consideration of its pathogenesis demonstrates a significant relation to organic diseases and to functional disturbances of the biliary tract. Etiologic agents incapable when acting individually of producing this disease may, when combined, assume a principal pathogenic role. Hemorrhagic, edematous, suppurative and gangrenous types of pancreatitis have been distinguished and each requires individual attention regarding diagnosis, prognosis, prophylaxis and treatment. There was a mortality of 17 per cent in the thirty-five operative cases of acute pancreatitis reported. Of these, 54 per cent were of type 1—acute edematous pancreatitis, a rather benign phase of the disease. Pain and tenderness, usually in the epigastrium or the upper part of the abdomen, were constant clinical observations. Radiation of pain to the back, vomiting and a history of similar recurrent attacks were elicited frequently. Incision and drainage of the pancreas combined with one or more ancillary procedures was carried out in 77 per cent of the cases. Use of the serum amylase test as an aid in diagnosis may tend to modify conservatively the future surgical treatment of acute pancreatitis.

- Bronchopneumonia of Unknown Etiology (Variety X): Report of Thirty-Two Cases with Two Deaths. W. T. Longcope, Baltimore.—p. 268.

Bronchopneumonia of Unknown Etiology.—Longcope describes the clinical course of the infection variously called atypical pneumonia, pneumonitis and bronchopneumonia. There is evidence of its contagiousness and it may be extremely severe. For convenience he designates the disease "bronchopneumonia, variety X". During the last few years he has observed thirty-two completely investigated cases. The ages of the patients ranged from 17 to 70 years. Seventeen were between 20 and 30 years of age. Twenty of the patients were men, eleven of whom were doctors, medical students, orderlies or hospital employees. Twelve of the patients were women and seven of these were nurses. The disease occurred at all seasons of the year, though eighteen cases were encountered during October, November and December. Ten cases occurred from May to September inclusive. Pneumococcic pneumonia is most prevalent in Baltimore from December to May, a period during which only eight of the cases under discussion were encountered. The incubation period is from about fourteen to twenty-one days. Usually the acute phase of the disease was preceded by a day or two of malaise with a rasping and nonproductive cough, and then fever accompanied by increasing cough, headache, general aches and discomfort, chilly sensations and occasionally abdominal pain and nausea. Only six of the thirty-two patients had an actual chill at onset. Five complained of pain in the chest, which was not sharp or stabbing and was rarely affected by respiration. Two had epistaxis as an early symptom. Four had pharyngitis due to beta hemolytic streptococci accompanying the onset of the disease. When the patients were first seen, often on the first to the third day of their illness, the temperature varied from 102 to 105 F. Usually the pulse rate and respiration were not proportionately elevated. The patients did not appear or feel very ill. The most annoying symptom was the rasping, nonproductive cough. Sometimes there was a small amount of sputum, which in a few instances was blood tinged but not rusty. The throat was sometimes reddened. The lungs during the first few days of illness usually showed no conspicuous abnormality, though a few patients presented a slight dullness over one or the other lower lobes, with suppressed breath sounds and a few fine rales over this area. A common characteristic of the disease in the early stages was a moderate leukopenia. The onset of the disease was similar in most cases, but the subsequent course varied from a mild infection to extreme gravity or fatality. The study throws no light on its etiology. Blood cultures made, often repeatedly, in twenty-seven of the cases gave no growth. The occasional occurrence in the sputum of a few nonpathogenic pneumococci which could not be typed can have little significance. The appearance of hemolytic staphylococci in the sputum during the latter stages of the disease in two cases suggests that secondary infections by pathogenic bacteria may occur. No serious attempt was made to isolate a filtrable virus, but experiments to accomplish this with the solidified lung in one of the two fatal cases resulted in failure. The reported results of such work by Reimann and by Francis and Magill are of uncertain significance, and the experience of Kneeland and Smetana shows that if a filtrable virus is the cause of the disease it has not been definitely identified. However, many features of the disease suggest a

filtrable virus. These are its contagiousness, the long incubation period, the inability to demonstrate any known pathogenic bacteria and the peculiarity of the pathologic pulmonary changes, for the exudate in the alveoli has been found to consist largely of mononuclear cells. The clinical features of the disorder appear sufficiently distinctive to allow one, even without knowledge of its etiology, to recognize the infection as a disease entity. Significant features for such an assumption are its characteristic onset, the prolonged persistence of symptoms and signs, the migration of the pulmonary lesions from one lobe to another, the biphasic elevation in temperature and the appearance of many fine, coarse or explosive rales during convalescence.

Electrolyte and Water Exchange in Bronchial Asthma.—Stoesser and Cook observed a group of children with persistent bronchial asthma in whom certain changes in the electrolyte and water balance caused definite variations in the degree of asthma. Placing the patients on a special low mineral, acid-ash diet which induced a low water retention improved the asthmatic condition, and subsequent artificial fever often caused the asthmatic symptoms to disappear. The remissions brought about by these procedures could be terminated by adding sodium chloride to the special diet or returning the patients to the general hospital diet, which was without salt restriction. During the periods of such diets artificial fever produced no consistent favorable influence on the asthma. These observations led the authors to determine the relationship between the electrolyte and water balance in the mechanism of asthmatic attacks. Pitressin offered a means of determining whether the increased water storage or the extra salt was instrumental in precipitating the symptoms. Pitressin, when injected subcutaneously, causes a retention of body fluids without the aid of an increase in body salts. Many asthmatic children were given pitressin, and six of them with intractable asthma who tolerated it were subjected to special studies. A total of twenty observations was made. The subjects were placed on an extremely low sodium chloride diet, and when pitressin was administered some retained as much as 2 Kg. (4½ pounds) of water. The asthma began to improve during the antidiuretic phase and continued through the diuretic and subsequent periods, proving that the storage of large amounts of water in the body and its sudden loss had little influence on the asthmatic symptoms. A review of the literature shows that during pitressin antidiuresis and diuresis, despite a low salt intake, sodium chloride is excreted, leading to a marked loss of body salt. It appears that bronchial asthma can be ameliorated, even in the presence of excessive hydration, if an associated depletion of sodium chloride exists. The authors draw no conclusions but point out that the study is of value as an investigative tool rather than a therapeutic procedure.

Histamine and Histaminase for Allergic Disorders.—

According to Alexander, evaluation of the therapeutic efficacy of histamine and histaminase for allergic disorders must be tentative for the present. Reported experience shows a rather striking similarity between the clinical effectiveness of the two. Neither appears to be of value for extrinsic allergy as asthma and hay fever, in which an immunologic mechanism is involved. Both are effective in urticaria, angioneurotic edema and physical allergy; that is, intrinsic allergy. This suggests that histamine operates through the production of histaminase. That intrinsic allergy responds to it and the extrinsic form does not leads to the question whether the H substance released by the one is qualitatively the same as that elaborated on contact between allergen and antibody. The question whether H substance is really histamine has been raised frequently and there are indications that the two are not identical. The limiting of histamine and histaminase therapy to intrinsic allergy, which is by far the more intractable type, shows sufficient promise to warrant further investigation.

Functions of Carotid and Aortic Bodies.—Schmidt reviews the knowledge of the functions of the carotid and aortic bodies. The function of these structures is to respond to changes in the chemical composition of the arterial blood by setting up afferent impulses which enter the central nervous system with the glossopharyngeal and vagus nerves, respectively. These impulses are stimulant to the medullary centers (respiratory, vasomotor and, in the case of the carotid body of the dog, cardio-inhibitory). The impulses from the stretch receptors of the carotid sinuses and aortic arch are inhibitory

to these centers (except the cardio-inhibitory, which is stimulated by them). The chemically sensitive receptors (chemoreceptors) can be stimulated by anoxemia, asphyxia, increased carbon dioxide tension or increased hydrogen ion concentration or by a variety of drugs and poisons. Reflexes from these structures are responsible for much, if not all, of the stimulant effects of anoxia on respiration and circulation. They probably are not concerned in the normal control of respiration unless the centers are depressed, in which event these reflexes become an important factor in maintaining respiration. An explanation that is in accord with existing information is that the chemoreceptors represent a survival in a relatively undifferentiated form of a reflex mechanism originally developed for a water-breathing ancestral form. The ability of these structures to set up a strong reflex stimulation to respiration when exposed to an environment that would depress or paralyze nerve cells (severe anoxia, high carbon dioxide tension or acidity, deep narcosis) is probably related to their primitive status and responsible for much, if not all, of their value to the organism.

Weil's Disease in the United States.—Blake points out that since 1935 sporadic cases of Weil's disease have been recorded with increasing frequency in the United States. In five of these the diagnosis seems to have been adequately supported by confirmatory laboratory tests, namely successful transmission of the infection to guinea pigs, demonstration of *Leptospira icterohaemorrhagiae* at necropsy or the development of specific agglutinins to a titer of 1:30,000. A number of other, less well documented, cases have been reported. The author cites the clinical history of a man aged 29 who, on Nov. 11, 1939, was suddenly seized with pain in the calves of both legs, weakness and dizziness. He developed chills, fever and headache and his neck became stiff and painful. He was nauseated and vomited frequently. His physician sent him to the hospital on the morning of November 12. On admission the patient appeared acutely ill, bathed in perspiration, pale, weak and apprehensive. The conjunctivas were injected, the lips and tongue were dry. The neck was stiff and painful. The lungs showed a few moist rales. The blood pressure was 96 systolic, 68 diastolic. There was tenderness of the abdominal muscles. The liver and spleen were not felt. All deep reflexes were slightly hyperactive. The abdominal reflexes were lacking. The Kernig test was negative. The white cell count was 27,350. A lumbar puncture showed an initial pressure of approximately 250 mm. of water. The fluid had a cell count of 30 per cubic millimeter, mostly red blood cells; a Pandy test was negative; a culture showed no growth. Blood cultures showed no growth. Agglutination tests for typhoid, paratyphoid and brucellosis were negative. The predominant symptoms during the first four days were prostration, fever, headache, meningismus and severe myalgia, principally in the neck, back and legs. On the third day epistaxes began, recurring at intervals until the thirteenth day. A second lumbar puncture on the fourth day revealed a clear spinal fluid under

normal pressure with 80 red blood cells per cubic millimeter. On the fifth day moderate jaundice developed; it lasted about a week. The liver became palpable and tender. From the tenth day on, the patient steadily improved. He was discharged on the nineteenth day for further convalescence at home, no diagnosis having been established. After returning home the patient again developed headache and soreness in the legs. His appetite was poor, and he felt drowsy and feverish. His vision seemed slightly blurred, and he vomited. On the twenty-seventh day of his illness he was again admitted to the hospital. A few days after admission, review of the clinical course of the illness suggested Weil's disease. The patient stated that about ten days before the onset of his disease he had been engaged in tearing down an old barn which was swarming with rats. Dark field examination of the urinary sediment, possibly too late for a positive result, failed to reveal leptospirae, but samples of blood serum collected on the thirty-eighth and forty-seventh days were reported to show complete agglutination with type 1 *Leptospira icterohaemorrhagiae* to a dilution of 1:10,000 and 1:30,000, respectively. Taken in conjunction with the history of exposure to rats, an appropriate incubation period and the typical course of the illness, the positive agglutination tests seem adequate to establish the diagnosis of Weil's disease. The author concludes that the more frequent recognition and diagnosis of Weil's disease depends on a wider appreciation of its prevalence, a greater familiarity with its clinical symptomatology, particularly that of the initial preicteric stage, and a more frequent use of laboratory tests of proved diagnostic value.

Malignant Melanomas.—Brown and Byars state that nearly every one has pigmented moles and that not all of them should be or need be removed. The safest procedure is to destroy all moles that are subjected to chronic irritation whether they are pigmented or not. Every lesion that shows evidence of growth, increase in vascularity, change of color, repeated infection or ulceration should be removed, as should be the smooth coal-black

nevi. The developmental mole that appears at any time during life and progresses in size is probably the type that most often becomes malignant. The removal of moles should be quick, painless, nonirritating and thorough and should involve minimal handling of the growth. The change from an innocent pigmented nevus to a malignant one should not be difficult to detect and diagnose. Early signs are an increase in elevation or surface area, deepening of pigmentation, increase in vascularity and an apparent chronic infection with slight tenderness. A new localized process in the skin or under the nail presenting an increase in bulk and lacking the pain and tenderness of an infection and the characteristics of a wart should be considered as a malignant neoplasm. Obvious melanin may not be present. Death almost never occurs from extension or erosion of malignant melanomas of the face and head, as may be the case in other malignant conditions of the face. This is probably due to the fact that hopeless metastases and death occur so rapidly. Treatment is limited to surgery, as melanomas are resistant to radiation. The surgical procedure should remove a generous margin of normal surrounding skin and the underlying subcutaneous tissue down to the fascia, and sometimes it may be necessary to sacrifice a facial nerve or the full thickness of the cheek. Melanomas require the earliest possible widespread removal to avoid metastasis; as to the time element in metastasis, one might almost compare hours in melanomas to weeks in other carcinomas following treatment of the local lesion. There are five possibilities: 1. The initial lesion may recur following removal or remain cured. 2. Metastases may occur in the adjacent skin varying from uniformly deeply pigmented velvety areas to stippled smutty patches. This is probably a precursor of widespread metastases. 3. The most hopelessly swift spread is the sudden appearance of skin metastases in many parts of the body, with or without evidence of visceral involvement. 4. The local lesion may remain cured but later, from a few months to twenty-five years, the patient may die of a visceral metastasis. 5. This group contains those cases in which the primary focus is eradicated and the metastasis appears in the regional lymph nodes and is held in check for some indefinite period. Radical block dissection of the neck has shown definite promise and gives the patient his only chance for life. If the primary lesion is located so that its lymph drainage is fairly predictable, a prophylactic dissection should be done. Eleven cases of malignant melanomas are cited. One of the patients has survived for seven, three for four years and the others only up to one and a half years.

Congenital Atresia of Extrahepatic Bile Ducts.—During the last five years Hicken and Crellin encountered five cases of congenital atresia affecting the biliary radicles and have devised an x-ray method to visualize the abnormal biliary tract at the time of operation, thus giving the surgeon a concept of the problem that confronts him. Corrective surgery which establishes a new channel for the flow of bile into the intestinal tract, thus decompressing the liver, offers the only hope of cure. It has been held that these cases were hopeless but recent studies indicate that from 20 to 30 per cent are amenable to surgery. The method of visualizing the ductal deformities at the time of operation employed by the authors is contrast roentgenography as used on adults to obtain exact anatomic patterns of the tract while the patient is on the operating table. These cholangiographic studies proved helpful in visualizing and locating the obstructive lesions affecting the diminutive biliary tract of the infant. The cholangiograms not only facilitated the classification of the obstructions but greatly aided the surgeons in selecting the proper remedial procedure.

Primary and Secondary Neurilemmoma of Bone.—That nerve sheath tumors frequently originate in bone and periosteum is well attested by occasional communications in the literature. There is a form of nerve sheath tumor the specificity of which is assured by a distinctive microscopic appearance and clinical behavior, which unfortunately is referred to by a variety of names (peripheral neurinoma, peripheral neuroma, neurofibroma, perineural fibroblastoma, schwannoma and recently by Stout as a neurilemmoma) indicating a diversity of opinion as to its histogenesis. In spite of an extensive survey of the literature dealing with this condition DeSanto and Burgess found only a

single brief reference by Gross, Bailey and Jacox to the undoubted occurrence of this tumor in bone. Peers described a cystic tumor located in the mid shaft of the ulna that would now be classified as a neurilemmoma. The prevalent concept that once a neurogenic tumor invades bone it is highly malignant and the possibility of cure is practically nil is fallacious and often leads to needless sacrifice of an extremity. The authors report two cases which showed extensive osseous destruction yet were undoubtedly benign. They do not intend to imply that malignant neurogenic sarcomas of bone do not occur. Every case must be decided on its own merits. Mere bone invasion by a neurogenic tumor is by itself inadequate to insure the diagnosis of a malignant tumor. The authors' first case is similar to the cases reported by Gross, Bailey and Jacox and by Peers in anatomic and x-ray appearance. They involved the mid shaft region of the bone, replacing portions of cortex and medullary cavity. The tumor found by Gross and his associates was removed by local excision, whereas DeSanto and Burgess treated the tumor by resecting a portion of the ulna. Finger-like processes of tumor tissue extended into the cortical bone in such a fashion as to leave doubt that simple excision would have proved adequate. Their second case was nonencapsulated and invaded the sacrum, indicating that occasionally the tumor may be locally invasive. Indeed, it even infiltrated the ligamentum flavum. Because of its location, complete removal was not possible and recurrence is anticipated. X-ray examination was done in both cases and cystic lesions with punched out cortical rarefactions were revealed in the first case. Neurilemmoma of bone is not to be confused with the less specific neurofibromas of bone in association with systemic and skeletal manifestations of von Recklinghausen's disease.

Partial Gastrectomy for Peptic Ulcer.—McClure and Fallis analyze the records of seventy-four consecutive partial gastrectomies performed for peptic ulcer which did not yield to medical treatment. The results justify the continuance of partial gastrectomy which removes from two thirds to three fourths of the stomach. The mortality for the group was 5.3 per cent and all deaths were due to peritonitis. No death has occurred among the last thirty-four patients in the series. The men outnumbered women nine to one. More than one half of the patients had submitted to previous operations on the gastrointestinal tract. Pain, and nausea and vomiting were the most constant symptoms, being present in 85.2 and 70.2 per cent of the patients, respectively. Roentgenograms were the greatest single aid to diagnosis. Among more than 90 per cent of the cases the x-ray observations were corroborated at operation. The ratio of duodenal to gastric ulcer was two to one, whereas the ratio among the authors' perforated ulcer series was three to one. One of the four patients who died did so after early postoperative complications developed; all survived late complications. The end result was excellent or good among 75 per cent of the patients. Carcinoma, suspected neither clinically

nor at operation, was diagnosed by the pathologist in five cases. The authors attribute their decrease in the mortality rate to improved operative technic resulting from increased experience and to the adoption of such measures as spinal anesthesia, routine blood transfusions during operation, continuous gastric suction in the postoperative period and oxygen during and immediately after the operation to avoid anoxia and to lessen the occurrence of pulmonary complications.

Aneurysm of Splenic Artery.—Literature contains record of only eleven cases of aneurysm of the splenic artery with survival after operation, according to Sperling, who cites a case in which this condition was considered preoperatively and recovery followed splenectomy and removal of the aneurysm. The pathologic report was that of a calcified arteriosclerotic aneurysm of the splenic artery. The classic x-ray picture described by Lindboe was present, leading to a correct preoperative diagnosis. Seven cases were found in the 33,810 necropsies performed at the University of Minnesota up to January 1939. Less than 100 cases have been recorded since the report of Crisp in 1847.

Cavernous Hemangioma of Spleen.—Cole and Forsee report what they believe to be the first successful outcome of a rupture of a cavernous hemangiomatous spleen, mistakenly diagnosed as acute appendicitis. Emergency splenectomy, performed seventeen hours after the onset of symptoms, proved successful. Hemangioma of the spleen is either a capillary or a cavernous primary vascular tumor. The first consists of a formation of dilated vascular channels in the splenic tissue which gradually become converted into tubules. In the cavernous type the capillary system is lost and the hemangioma consists of a series of freely intercommunicating spaces of varied sizes, lined with endothelium. They are usually considered congenital. Usually the symptoms of benign hemangiomatous spleen are of long duration and are characterized by a gradually increasing tumefaction in the left hypochondrium, associated with pain, loss of weight and anemia. Surgery is the only curative therapy, and splenectomy is necessary. The twenty-two previously reported cases of benign hemangioma of the spleen are tabulated.

Local Operation for Early Breast Carcinoma.—Fitzwilliams presents data to show that local excision of really early mammary cancer is justifiable. He defines an early carcinoma as one in which there is a faintly perceptible something in the breast—hardly a lump and certainly not a tumor. These tumors have one invariable characteristic: they throw a shadow on strong transillumination. If such a shadow is seen, nine times out of ten the tumors will be carcinomatous. Strong transillumination is the only method of diagnosing them. Of ninety-three patients suitable for the conservative procedure five were lost track of, sixty-two are living and twenty-six are dead. Of the five patients lost track of one went to Argentina the same year, one was lost sight of after eight years and one was known to have kept well for one year and eight months, one for three years and three months and one for nine and a half years. Of the sixty-two living patients forty-seven had no recurrences. The longest survival among these forty-seven patients is fourteen and a half years. Twelve patients have lived longer than ten years and eighteen between five and ten years. Of the fifteen living patients who have recurrences, three have distant but no local manifestations and twelve have local recurrences. The average survival time of these patients has been ten and one half years, varying from two years and eight months to nineteen years. Recurrences appeared locally in an average of two years and nine months. Of the patients who died, twelve did so of intercurrent disease, eleven died of carcinoma but without local recurrence and three died after local recurrence but not necessarily because of it.

The survival time of these twenty-six patients ranged from six months to twenty-four years. The average survival was more than six years. The author points out that casual observation of many of the patients would not have disclosed the fact that the breast had been operated on. After operation constant vigilance on the part of the doctor, and the willing cooperation of the patient, are necessary. The author's contention is that local operation in really early cases of mammary cancer can confer the same amount of safety as the more extensive operation.

Tuberculosis of Knee Joint in Adults.—Key discusses the general aspects of the tuberculous knee joint. All but nine of 108 patients treated at St. Luke's Hospital, Lowestoft, from 1931 to 1935 have been followed up recently. Of these patients 37.75 per cent had tuberculous lesions elsewhere. History of trauma, probably bearing some relation to the development of the tuberculous joint, was elicited in 15 per cent of the cases. The average interval from the injury to the onset of symptoms was four and a half months. By the time the diagnosis is made, pathologic changes in a tuberculous knee joint have passed the earlier stages of disease. This was the fact in 87 per cent of seventy-seven cases of recently developed osseous disease, increasing subsequently to 96.1 per cent. Focal osseous disease by itself undergoes three principal changes: 1. The disease remains comparatively localized and reaches quiescence; bone cavities become obliterated or remain circumscribed by well calcified bone. 2. The disease extends laterally and causes abscess formation in the soft tissues. 3. The diseased area extends downward. This is the most common occurrence, and once the joint becomes grossly infected the later destructive changes progress until quiescence is eventually established. In repair fibrosis is the predominant factor. Pain is the first symptom in 70 per cent of cases. Swelling of the joint with pain or stiffness is present in 54 per cent of patients when medical advice is first sought. In a further 22 per cent the initial abnormality noticed by the patient was a swelling of the knee. Limitation of movement is gross and is accompanied by spasm when the joint surfaces are eroded. Tenderness, when present, is most often elicited on the inner side of the joint. Local warmth is always present. Abscess formation in the early stage of the disease occurs in 6.5 per cent. X-ray changes in the early tuberculous knee joint are usually inconclusive. One or more of the following abnormalities are usually seen: (1) general haziness, (2) increased width of the soft tissue shadow, (3) osteoporosis, (4) diminished joint space and (5) lack of definition or thinning of the cortical bone. After an average interval of four months from the onset of symptoms an abscess cavity or cavities are usually present in bone; localized marginal erosion may also be seen. Destructive osseous changes are more advanced than they appear on x-ray examination. Early diagnosis is difficult. It is justifiable to treat an obscure case of subacute arthritis as potentially tuberculous until proved otherwise. The insidious onset of joint symptoms is important, as is their spontaneous alleviation, which is never complete. The patient's general physical condition is an untrustworthy guide, as in 87 per cent it is good or only slightly deteriorated. Bacteriologic examination of pus from an abscess is the most valuable laboratory aid. Biopsy of the synovial membrane is inadvisable. In adults, tuberculosis of the knee joint may be confused with subacute chronic infective or gonorrheal arthritis, syphilis, hemophilia, traumatic lesions and neoplasms. Conservative treatment is indicated when the disease is purely synovial, when the bone focus or foci are removed from the articular margin and are surrounded by healthy bone, in quiescent cases with widespread osseous involvement and when other active tuberculous lesions exist. Conservative treatment appeared to suffice for only thirty cases. Thirty-one of the 108 patients returned to the hospital, indicating that free movement or bony ankylosis should always be sought. Arthrodesis, after arrest of the general illness and local disease, is the best treatment for most cases. Active septic infection of sinuses and persistently active local disease are its chief contraindications. Bony union was obtained in 83 per cent of fifty-nine cases. The five cases in which firm fibrous ankylosis resulted have remained functionally excellent, but the result must be regarded as having fallen short of the objective.

Two incomplete fibrous unions and three nonunions (two of which subsequently required amputation) were chiefly due to operating when the disease was active. Three of the ten patients having amputations died within a few days of operation, three survived operation and left the hospital but have died at varying intervals since, and four patients are well. Amputation is a last resort, but the tendency is to delay it too long. A patient suffering from profound toxemia has often passed the stage when amputation could have saved his life. Widespread disease may exist with remarkably little constitutional disturbance and amputation should not be performed until prolonged conservative treatment has failed to give any sign of recovery.

*Carcinoma of Stomach in Young Subjects. J. G. Macleod and R. B. Baird.—p. 627.

Carcinoma of Stomach in Young Subjects.—Macleod and Baird state that ten cases of gastric carcinoma in persons 30 or less years of age occurred among 700 cases of carcinoma of the stomach treated since 1934 at the Royal Infirmary, Edinburgh. Some of the observations in these cases differ from those reported by other workers. Six of the ten cases occurred in women, in contrast to Bruckner's report that men were affected twice as often as women. Microscopic confirmation was obtained in six cases, and the tumors in four were adenocarcinomatous, one scirrhous and one medullary. The pyloric antrum of eight was involved, the lesser curvature of one and the whole of the stomach of one. No particular disease, certainly not peptic ulcer, was simulated, and the characteristic course (in seven cases) commenced with a period of vague dyspepsia in which abdominal pain was a common feature. All this is contrary to the observations of Bruckner. Vomiting was present in nine cases; it tended to occur later and to be of an obstructive type. Pyrexia was uncommon, being persistent in only one case. A mass, far from being infrequent, was palpable in seven cases. This is in keeping with the observations of Phillips in that in those cases in which the tumor was measurable it was greater than 6 cm. in diameter at operation of 73.6 per cent of the patients. In keeping with Bruckner's observations the average duration of symptoms prior to admission was fifteen and one half weeks and from onset of symptoms to death sixteen and one half weeks. Local metastases were present in nine of the ten cases, and metastases were widely disseminated in three of the six cases examined post mortem. The outcome was uniformly fatal. In Phillips's series metastases had already involved the lymph nodes in two thirds of the cases and other metastases were found in an unusual variety of sites. The authors emphasize the short course, the extensive metastases and the hopeless prognosis and point out that the condition, while uncommon, is not as rare as is usually thought and therefore the ruling out of gastric cancer because of the youth of a patient suffering from an anomalous type of dyspepsia must be avoided. In such cases the routine use of the flexible gastroscope may aid a diagnosis to be made sufficiently early so that radical but probably beneficial surgery may be carried out.

Chronic Jejuno-Ileal Insufficiency.—Bennett and Harwick direct attention to the fact that the last twenty years have seen the increasing recognition of a clinical syndrome of steatorrhea, tetany and macrocytic anemia. The names of Gee, Herter, Heubner and Thaysen have been attached to it; celiac disease and tropical sprue fall within its definition. There is a tendency to class together as nontropical sprue all such cases not coming from the tropics. The syndrome is also found in some cases of malignant or of cicatrizing disease of the small intestine, in some cases of gastrocolic fistula and in some cases of tabes mesenterica. Rickets and deformed bones are common when the syndrome affects children. The anemia is hypochromic or erythroblastic; stomatitis and sore tongue are common; skin lesions, including some resembling those of pellagra, have been described. The fatty diarrhea is notable in that the fat is fully split, and the stools may be bulky and pale but not frequent. In other cases the stools are frequent and gassy; megacolon, perhaps compensatory, is pronounced in some cases. When the syndrome begins in childhood there is stunting of growth, often accompanied by infantilism. When it begins during adult life it is usually accompanied by sterility. Blood calcium and blood phosphorus are often low. In spite of the attempts to recognize in this syndrome a single entity, it seems clear that two diseases in no way related to each other, celiac disease and tropical sprue, are responsible for the vast majority of examples. The following points are important in differentiating between these two conditions: Celiac disease essentially affects little children. Tropical sprue is essentially a disease of adult life. Celiac disease produces meteorism, but in its later stages the stools tend to be pale and bulky rather than frequent; stomatitis and sore tongue are rare; megacolon is common in the older patients. In sprue the feces tend to be more fluid, and the diarrhea responds more rapidly and completely to treatment. Sore tongue and stomatitis are the rule; megacolon seldom if ever develops. Tetany is common in both conditions, but rickets and deformed bones are found in celiac disease alone. The anemia of celiac disease is usually hypochromic. In tropical sprue, macrocytic anemia is common. Established celiac disease is fatal to 40 per cent of the patients during the first two years, and of those who survive the early stages not more than 25 per cent reach the third decade. Tropical sprue, properly treated, gives an extremely good prognosis. Even in the present incomplete state of knowledge it is important to recognize that in every example of this syndrome the clinical picture is due to the same cause; that is, chronic jejuno-ileal insufficiency, with consequent defects of secretion and absorption. The final proof of this is provided by cases in which the small intestine is deprived of its functions by surgical short-circuiting.

Treatment of Epidemic Poliomyelitis with Potassium Chlorate.—Gsell calls attention to the administration of fractionated doses of potassium chlorate in the treatment of poliomyelitis, a method recommended by Contat (*Schweiz. med. Wchschr.* 68:669 [June 4] 1938; abst. THE JOURNAL July 23, 1938, p. 363). An epidemic of poliomyelitis during 1939, in the course of which 119 cases were observed at Gsell's clinic, gave him an opportunity to ascertain the efficacy of Contat's therapy. Gsell employed potassium chlorate in ninety-seven cases. He presents a number of clinical histories which provide answers to the essential questions that arise in connection with every form of treatment recommended for poliomyelitis. He observed that potassium chlorate exerts no influence on the severest form of poliomyelitis with ascending paralysis. The temperature remains high, the paralysis advances and death takes place. The question whether early potassium chlorate therapy is capable of arresting the process in the preparalytic stage and thus prevent paralysis is likewise answered in the negative. Early potassium chlorate treatment failed to prevent the development of serous meningitis in nonparalytic cases. The fever remained high in spite of the administration of potassium chlorate. Comparing the cases treated with potassium chlorate with cases observed in previous epidemics in which Contat's method was not employed, the author found that the percentage of nonparalytic forms was practically the same. The mortality rate was 6 per cent in the cases treated with potassium chlorate and 1.5 per cent in the other cases. The percentages of complete cure and of crippling defects were about the same whether potassium chlorate was given or not. The author thinks that the higher mortality rate in the cases treated with potassium chlorate is not the result of the treatment but that it indicates that this therapy has no effect on the course of poliomyelitis.

- *Regulation of Hemopoiesis in Pathogenesis of Pernicious Anemia: Action of Liver Extract on Basal Metabolism in Pernicious Anemia. G. Boccuzzi and W. Paolino.—p. 489.
 Aminopyrine and Diuresis. C. Franzolin.—p. 511.

Pernicious Anemia.—Boccuzzi and Paolino studied the behavior of basal metabolism in twenty cases of pernicious anemia. The basal metabolism was increased in thirteen and diminished in one case before the employment of liver therapy. It displayed a tendency to become normal after ten or more days of liver therapy. Nine patients were given an intragluteal injection of 4 cc. of liver extract before liver therapy and again in the course of treatment. The consumption of oxygen for the first four hours following the injection progressively increased when the basal metabolism was normal, diminished and then increased when there was basal hypermetabolism and varied slightly in the presence of hypometabolism. Because of the influence of liver extract on pernicious anemia and the frequency of basal metabolic disorders on the one hand and the relationship between the thyroid, hemopoiesis and basal metabolism on the other, the author associated thyroid disorders with the pathogenesis of pernicious anemia. He presupposes the existence of two hemopoietic antipernicious factors, Castle's factor and a hepatothyroid factor. Both factors are stored in the liver and are essential to normal hemopoiesis. The insufficiency of both factors, or the insufficiency of one in the absence of the other, is the cause of a disturbance in the regulation of hemopoiesis

with consequent pernicious anemia. A predominant insufficiency or absence of the Castle factor stimulates overproduction of the hepatothyroid factor with a partial or total reaction on the part of the thyroid. If the reaction is partial, the basal metabolism is normal in the presence of pernicious anemia. If it is total, there is basal hypermetabolism. A predominant insufficiency of the hepatothyroid factor indicates functional or structural insufficiency of the thyroid associated with basal hypometabolism. The tendency of the basal metabolism to return to normal on liver therapy suggests utilization of the antipernicious factors contained in the liver extract and the reestablishment of the hemopoietic function of the organic antipernicious factors. The Castle factor is not related to the consumption of oxygen by the body immediately on administration of liver. The hepatothyroid factor exerts an indirect effect on the consumption of oxygen through the thyroid. The different curves of oxygen consumption immediately after an injection of liver extract indicate a more or less rapid utilization of the antipernicious factors by the body. A constantly increasing curve of oxygen consumption in the presence of normal basal metabolism indicates a moderate insufficiency of the Castle factor, a partial thyroid reaction and immediate utilization of both antipernicious factors. An early downward curve of oxygen consumption followed by a late upward curve in the presence of basal hypermetabolism indicates acute predominant insufficiency of the Castle factor, a total thyroid reaction, early utilization of the Castle factor and late action of the hepatothyroid factor. A slow progressive upward curve of oxygen consumption in the presence of basal hypometabolism indicates a moderate insufficiency of the hepatothyroid factor from functional thyroid insufficiency and an immediate, although slow, organic utilization of the hepatothyroid factor. Slight variations in the curve of oxygen consumption in the presence of basal hypometabolism indicate insufficiency of the hepatothyroid factor due to structural insufficiency of the thyroid.

- Sulfanilamide in Therapy of Infections of the Eyes. D. Cattaneo.—p. 231.
 *Toxicity of Sulfanilamide for Liver. G. De Bonis.—p. 248.

Toxicity of Sulfanilamide for Liver.—De Bonis observed symptoms of liver intoxication develop in the course of the first week of sulfanilamide therapy in two cases. Gonorrhea in one case and diplococcic tonsillitis in the other were mild and were in a stage of regression when the treatment was instituted. The patients had never complained of liver disorder. The daily dose of the drug was 1.8 Gm. The patients complained three or four days after the beginning of the treatment of nausea, digestive disturbances, headache and a dull pain in the region of the liver. These symptoms were followed from two to three days later by jaundice, urobilinuria and enlargement of the liver. The blood was normal. The drug was discontinued and a proper diet and treatment instituted. The symptoms, however, became more acute, fever developed, lasted one day, abated after spontaneous sudation and was followed by urticaria in one case and by a cutaneous rash in the other. The condition was controlled in two weeks by diet and by appropriate treatment, intravenous dextrose, calcium and liver therapy. The author studied the effect of sulfanilamide on the liver in eleven normal persons who received a daily dose of 0.03 Gm. for each kilogram of body weight for ten consecutive days. Liver function before and after administration of sulfanilamide was determined by the aminoacetic acid and dextrose tolerance tests. Disturbance of liver function was demonstrated in five cases. The author concludes that sulfanilamide has a toxic effect on the liver in a large percentage of cases. It is therefore suggested that particular attention be paid to hygiene and diet before and during administration of the treatment, the dose and duration of which are to be directed by the physician. It is likewise advisable to watch liver function in the course of the treatment, especially in cases in which there is a previous history of liver disorder.

*Strophanthus in Heart Disease. S. G. Jucker.—p. 545.
Roentgenograms of Venereal Lymphogranulomatosis in Anus, Rectum and Colon. M. Buisson and A. Midana.—p. 550.

Strophanthus in Heart Disease.—Jucker administered strophanthus intravenously in seventy-five cases of decompensated heart of various types, such as those due to valvular disease from rheumatic endocarditis, to myocardial sclerosis or to syphilitic chronic aortitis with an anginal syndrome and to failing of the pulmonary circulation due to sclerosis of the pulmonary artery and acute insufficiency of the heart. The treatment was resorted to after failure of digitalis or in cases of intolerance to digitalis. The initial dose amounted to 0.0001 or 0.0002 Gm. of the drug. The total daily dose did not exceed 0.00025 Gm. in disturbances of the coronary circulation, acute heart insufficiency or grave myocardial alterations complicating infections, and it was 0.0005 Gm. in cases without these disturbances and with hypertrophied heart. The drug was administered every other day or at longer intervals, and the total number of doses varied from four to ten. The treatment was repeated in some cases on reappearance of the symptoms of decompensation three or more months after the first treatment. It was well tolerated in all cases. Circulation and the general condition of the patients improved. Oxygenation of venous blood in valvular disease or of arterial blood in sclerosis of the pulmonary artery improved. Diuresis increased and edema was controlled. Dyspnea and cyanosis were controlled or greatly improved. The anginal syndrome in chronic syphilitic aortitis was controlled. The electrocardiogram became normal in cases of valvular disease. It improved in some cases of myocardial disease and did not change in syphilitic aortitis. The treatment is harmless, provided it is given in a proper dose and according to proper indications. Certain types of heart insufficiency are associated with cardiac hypersensitivity to strophanthus. The individual sensitivity is determined by the reaction of the patient to small doses of 0.0001 or 0.0002 Gm. of the drug. The author considers acute insufficiency of the heart as an absolute indication for strophanthus therapy. The presence of moderate renal disease or of complicating myocardial sclerosis does not contraindicate the treatment. Addition of dextrose, caffeine or ethylenediamine does not modify the pharmacologic properties of the drug.

Adenoma of Kidney: Case. P. G. Curbelo.—p. 313.

*Nutritional Edema. A. Ortiz.—p. 319.

Nutritional Edema.—Ortiz emphasizes the role of lack of proteins and vitamins A and B₂ in the diet in the development of nutritional edema frequently seen in Puerto Rican infants and children. Twenty-seven children with nutritional edema observed by the author were anemic and undernourished and they complained of general debility. Five patients in the group vomited, twenty-five had chronic diarrhea, and several suffered from pellagra, celiac disease, intestinal parasites, infectious fever, chronic bronchitis and multiple infections. One had pulmonary tuberculosis. The treatment consisted of a diet rich in proteins and of administration of vitamins A and B₂ and, in grave cases, of liver extract, iron and blood transfusion. The proteins in the blood plasma were determined before and after the treatment in nine cases, in all of which, except those complicated by renal disease, the total proteins and albumins in the blood were increased coincidentally with the control of edema by diet and treatment. In cases of nephritis or nephrosis the treatment controlled edema but the blood proteins did not increase. A differential diagnosis between nutritional edema and renal disease is important because restriction of proteins, which is indicated in the latter, aggravates the former. Patients with early nutritional edema react promptly and favorably to the treatment and diet. The diet must be supervised when the patient returns to his home because of poverty and lack of understanding of the causes of the condition. The lack of a proper diet results in reestablishment of edema. Two necropsies revealed anatomopathologic evidence of lack of vitamin A and of the occurrence of multiple infection.

Femininity Causing Effects of Adrenal Tumors in Men. O. Pico Estrada.—p. 807.

*Relationship Between Chronic Mastitis and Cancer of Female Breast. S. Warren.—p. 829.

Chronic Mastitis and Cancer of Female Breast.—Warren studied 1,044 women who had chronic mastitis and in whom a portion of the involved breast was removed and was subjected to microscopic study. The group included cases of chronic simple and cystic mastitis, Schimmelbusch's disease, Semb's cystic fibro-adenomatosis, Cheate and Cutler's hyperplasia, Aschoff's cystic mastopathy and Reclus's disease. The patients were observed for an average period of nine years after the operation. Cancer of the involved breast did not exist in any case at the time the operation was performed. It developed in thirty-five cases some time after the operation. The author found that the incidence of cancer of the breast was six times as great in women who have had chronic simple or cystic mastitis as in those who did not have this condition. It was greater in women above the age of 30 and before the menopause than in those at the menopause or after. There exists a relationship between chronic mastitis and the development of cancer, although either condition may develop in the absence of the other. The treatment of chronic simple or cystic mastitis consists in excision of the involved portion of the breast. The patients should be observed for a long period after the operation. The appearance of nodules or cysts in the remaining portion of the breast is an indication for a unilateral mastectomy. A bilateral mastectomy is not justified as a preventive measure in cases of chronic simple or cystic mastitis.

*Failure of Indigo Carmine Test and Significance of Acid-Alkali Alteration Test According to E. Rehn for Diagnosis of Renal Tuberculosis. Annemarie Schneider.—p. 157.

Renal Injuries. P. Deuticke.—p. 165.

Cleansing, Sterilization, Drying, Hardening and Storage of Urethral Catheters. W. Wicher.—p. 173.

Prostatectomy or Resection of Prostate?—Kneise cites a number of recent publications on the question of enucleation versus electroresection of prostatic hypertrophy. He considers the enthusiasm for the transurethral electrocoagulation and electrotomy as premature. In an earlier evaluation he had expressed the opinion that electrocoagulation is excellent for the soft tumors but that in hypertrophy of the prostate the method will not produce such wonderful results, for, he is convinced, the extremely favorable results reported by some are due to the fact that electrotomy was employed in cases which would have responded to catheterization. He cites authors who greatly restrict the indications for electroresection and quotes statistics from Rehn's clinic in Freiburg which reveal that the percentage of patients subjected to electrocoagulation has steadily declined in recent years. On the basis of thirty years of experience he himself favors a two stage prostatectomy. With this method he has been able to save patients who at first seemed unsuited for the operation. However, some times he has waited as long as six or nine months to give the kidneys time to recover sufficiently, so that the intervention could be made without danger. He admits that prominent surgeons state that from 25 to 30 per cent of their patients cannot be rendered suitable for operation and that for these they wish to employ electroresection, but he thinks that this is due to the fact that they do not evaluate properly the temporary vesical fistula. He stresses the advantages of the vesical fistula and describes his method of effecting the gradual closure of such a fistula. He believes Kraas justified in stating that it is not advisable to treat all forms of prostatic adenoma with the same method, and that the possibility of individualizing the treatment signifies progress of prostatic surgery. Large adenomas of the prostate should be radically removed by prostatectomy, provided the case is suitable for operation.

Rehn's Acid-Alkali Alteration Test.—According to Schneider the acid-alkali alteration test was first described by Rehn and Günzburg in 1923. Since then it has been employed in about 4,000 cases at the surgical clinic in Freiburg. Rehn's acid-alkali alteration test examines the capacity of the kidney to eliminate acid and alkali and to reabsorb the necessary alkali. The acid elimination is tested in the morning with the patient fasting. One hour before the examination the patient is given 300 cc. of water and twenty-five drops of diluted hydrochloric acid. A rack with two sets of test tubes (one set for the urine from each kidney) is prepared. Cystoscopy is done and ureteral catheters are introduced. The pH value is determined with five drops of urine from each kidney. Then follows the alkali tolerance test, 50 cc. of a 4 per cent solution of sodium bicarbonate being injected intravenously. Three minutes later and at intervals of three minutes (until twelve minutes has elapsed), urine is obtained from both kidneys and the pH of the specimens is determined. It is absolutely necessary that only those specimens be compared which were excreted simultaneously by the two kidneys. The kidneys of a healthy subject excrete at the same time urine of an identical reaction, but even slight differences are pathologic. Thus in the evaluation of the curve obtained by the acid-alkali alteration test the absolute pH values are less important than the functional latitude (the change after the alkali tolerance test) and especially the comparative values of the two kidneys. The author believes that the determination of the pH values is the chief reason why the method has failed to obtain the wide application it deserves. Rehn's modification of the indicator method of Michaelis is the best for practical purposes. In case of extensive glomerular impairment the acid-alkali alteration test discloses a persistent acidity (acid rigidity). The impaired glomeruli are throttled. The flooding of the blood with an alkali produces no change, because a better elimination is impossible. The urine remains acid. In case of slight glomerular damage the acid rigidity is relative; the curve of the diseased kidney remains below that of the healthy one. In case of tubular lesions, although the glomeruli eliminate the acid and alkali the diseased tubules fail to reabsorb alkali and already the initial value of the diseased kidney is at the neutral point or in the alkaline sphere, and after the alkali tolerance test the alkali values become extremely high. If glomeruli and tubules are impaired, the reaction of the renal urine is from the beginning near the neutral point or in the alkaline region. The acid-alkali test is extremely sensitive. It has proved especially valuable in the diagnosis of renal tuberculosis, disclosing disorders not detectable by other tests.

Acid-Alkali Alteration Test in Renal Tuberculosis.—The diagnosis of renal tuberculosis is generally based on the presence of renal pyuria, disordered renal function and tubercle bacilli in the renal urine. Tubercle bacilli cannot always be demonstrated in the presence of renal tuberculosis. In such cases the diagnosis is made on the basis of functional kidney tests combined with evidence of destruction in retrograde pyelograms. At Rehn's clinic, according to Schneider, the diagnosis is never based on the pyelogram alone or on the functional tests alone, for neither alone permits of a reliable diagnosis. If both are positive, renal tuberculosis can be recognized even if no bacilli can be demonstrated. Extreme caution is necessary in the interpretation of roentgenograms, because there exist non-tuberculous inflammatory lesions in which the changes in the papillae may resemble those of an incipient renal tuberculosis. Differentiation is possible because renal tuberculosis is always accompanied by permanent disturbances in the renal function, whereas the nontuberculous papillitis may heal and the function may become normal. Since functional tests are of decisive importance in the diagnosis of renal tuberculosis, their reliability was investigated and it was found that the indigo carmine test often simulates a normal function when the acid-alkali alteration test of Rehn discloses a functional impairment. The more reliable acid-alkaline alteration test has not found the wide application it deserves, because the impression prevails that it is too complicated. The author feels that this impression is not justified. She presents a number of case histories which demonstrate that Rehn's acid-alkali alteration test is definitely superior to the indigo carmine test, for whereas the indigo carmine test simulated a normal renal function, the acid-alkali alteration test disclosed a functional disturbance of the diseased kidney.

*Bone Destruction in Cancer of Cervix of Uterus by Direct Propagation, by Lymphogenic and by Hematogenic Metastasis. F. Nørgaard.—p. 1271.

Bone Destruction in Cancer of Cervix.—Nørgaard says that x-ray examination of the skeletal system, especially of the lumbar spine and the pelvis, in patients with cancer of the neck of the uterus treated at the Radium Station in Copenhagen shows that the changes consist almost exclusively in osseous destruction, in a few cases with sclerosis. Since propagation or recurrence of the cancer almost always occurs in only two ways, either to the parametrium or to the lymph glands along the vasa iliaca and the abdominal aorta, there are two well defined main groups of osseous changes. When there is metastasis to the parametrium the earliest changes appear in the iliopectineal line and consist of a flat irregular gnawing off a few centimeters in extent, usually localized to the posterior half, occasionally with sclerosis. In more advanced cases the iliopectineal line is frayed or gnawed off, with larger or smaller clarifications, often sharply defined, from the sacro-iliac articulation to the pectineal line and upward on the inner side of the ala of the ilium. Every small clarification in the iliopectineal line must be suspected as possibly the earliest faint sign of destruction. In the second main group, with metastasis to the regional lymph glands, the tumor tissue may invade the adjacent bones; in the ala of the sacrum and parts of the ilium bordering on the sacro-iliac articulation clarifications appear, and in the lumbar vertebrae, most often the fourth and third, destruction occurs in the lateral surfaces of the bodies, usually unilaterally. There may be extensive destruction in several vertebrae. Hematogenic metastases to bone are rare. The author has seen five cases in fourteen years, two of which were localized to the femur, two to the tibia and one to the tarsus. In one of the cases roentgen irradiation resulted in recovery; the patient has been without symptoms for over four years. He cautions that the osseous changes described must not be confused with changes in the neck of the femur resulting from roentgen irradiation and causing spontaneous fractures and pseudarthroses.

*Traumatic Pulsating Exophthalmos and Its Treatment. E. Schie.—p. 1275.

*Neuro-Anatomic Examination of Brain After Ligation of Carotid Artery in Case of Pulsating Exophthalmos. J. Cammermeyer.—p. 1283.
Fracture of Spinal Column After Metrazol Shock Treatment of Psychoses. A. Vogt.—p. 1289.

Traumatic Pulsating Exophthalmos and Its Treatment.—In the first of Schie's patients, a man aged 36, the symptoms disappeared for a week after ligation of the right internal carotid artery on the same side as the aneurysm. They again disappeared after ligation of the left internal carotid and the patient felt well for four days. An apoplectiform hemiplegia of the right side then occurred, with fatal outcome. In the second patient, a woman aged 41, ligation of the internal carotid on the same side as the aneurysm was done. While normal eyesight was not restored, the other symptoms disappeared and she is able to work. The third case is one of untreated pulsating exophthalmos of six years' standing.

Neuro-Anatomic Examination of Brain after Ligation of Carotid Artery.—Cammermeyer's examination in the first of Schie's cases of pulsating exophthalmos showed a considerable degenerative process in the left hemisphere, limited to the cortex within the motor area and the adjacent convolutions. The cellular changes were of the "severe" (Nissl) and the "homogenized" (Spielmeyer) types. The glia cells in part showed regressive changes with pyknosis and karyorrhexis, in part milder "progressive nuclear changes." The author concludes that following the ligation of the carotid on the left side a considerable necrosis of the cortex, ascribed to a probable embolic process, occurred corresponding to the end branchings of the middle cerebral artery. In the intensity and nature of the changes and their limitations the case resembles the cases examined by Müller and Döring, but it differs from them in that the pathologic changes are cortical without involvement of the white substance or the basal ganglions. The onset of symptoms an interval after the operation also suggests an embolic pathogenesis.

DaCosta—Man and Genius

FREDERICK E. KELLER, M.D.

PHILADELPHIA

Every so often a truly great soul or character is born, one who is extraordinary and grand and whose mental ability shines out with the seeming brilliance of the noonday sun, rendering all around refulgent with its scintillating rays. Occasional fleeting shadows may dim the rays and give a hasty glimpse of those characteristics, showing that genius is just human and that such a giant is, after all, akin to us poor ordinary mortals. Occasionally too one may be privileged to tread the pathway carved by such a genius or at times walk beside him and see and attempt to analyze some of those characteristics.

For only a short time was I privileged to stand near such a genius and to observe him for a few fleeting moments, but those fleeting moments have made a lasting impression—a bright ray—a beacon outshining the light of other knowledge that has come to me. I refer to that genius of pen and scalpel, that master of oratory, that omnivorous reader, that great philosopher, that almost matchless mind and yet very human J. Chalmers DaCosta. A definite and unswerving teacher who hated an ice bag in appendicitis with the same vehemence that he hated lawyers who browbeat the physician on the witness stand, to whom a fire or a fireman meant more than a fat fee and to whom the gratitude of a ward patient meant a greater personal satisfaction and recompense than the dollars of the wealthy. A man whose force of knowledge, will power and deft fingers stalked, time and time again, the grim specter and won on that twin field of tragedy and pathology called the operating room.

His book on surgery, true to his teachings, was and still is a revelation and a masterpiece. The usual dry preface was replaced by an entertaining essay, varied in each edition and showing the diversified knowledge of the author in arts and sciences as well as an understanding of what would appeal to all classes of readers.

TRIALS AND TRIUMPHS OF THE SURGEON

Stories always crop up about such an individual—some true, some spurious—but each serves to emphasize the personal element. They

never detract; they serve to delineate and cause him to stand out in bold relief both among his contemporaries and in the times and greatly accentuate the God-given genius in his mortal habitation. No better illustration can be used in the opening pages of this character sketch than some of the remarkable figures of speech, comparisons and descriptions used in one of his speeches, notably *Trials and Triumphs of the Surgeon*: "When a surgeon is too old to be of much value they make him a consultant, but when a lawyer is ready for the shelf he is placed in the Supreme Court. When I see his honor, the judge, on the bench, with his arcus senilis, tortuous temporal arteries and other signs of degeneration, I think of the fly in the amber; I see him, I know he is there, but how did he ever get there?" To quote further: "It is vastly to the credit of the medical profession that so few leave it to go into quackery; . . . if a regular chooses to apostasize and then turn quack he can often make money rapidly and in quantity, but few are willing to become pariahs. The old training has left its mark. Certain beliefs are fixed so firmly that they become as intuitions. A man may leave the army of healing but he seldom joins the enemy. . . . Failure, disappointment, disenchantment, embitterment, neglect, even actual want very seldom cause a physician to become a quack and thus cease to be a man who stands above the common herd." "Of all the causes of failure I doubt if any is more potent than vanity. The proper attitude towards all scientific questions is one of humility. When one can no longer wonder at nature, he can no longer progress. When he would settle everything by a formula, he is consigned forever to the compartment of useless odds and ends." "Vanity tires out even the most patient colleague, gives a weapon to every opponent, and potential friends quickly weary of the society of the discoverer of everything that is useful and important. Such men obey the command to let their light shine before men, and it shines so strongly and persistently that it resembles a conflagration in a shop of fireworks.

It may be added that those about find their nostrils assailed with noisome odors and their ears bombarded with sounds of destruction. Were the walls which bar the way to success like the walls of Jericho, they might be expected to fall from noise, but they do not do so. The man who does the bombarding is of small caliber in spite of being a big bore. Every now and then we see such a man purchase a two-cent stamp as though he were laying the cornerstone of a cathedral. Such a vanity makes one suspicious, critical, resentful, ungrateful and bombastic. The athletic exercise of throwing bouquets at oneself never strengthens the muscles of the mind. When it is practiced for a long time, a man sets as exaggerated an estimate on his own value as though he were suing a railroad company for damages. Such a man can't obtain real success, but he may get rich, because he may persuade the general public to take him at his own estimate."

"The vain man in surgery is a deadly peril. He mistakes his own half-formed opinions for the oracles speaking within him. He is never conscious of his mistakes and hence keeps on making them. He misleads others by his positive assertions regarding unproved views. He clamors insistently for credit. What he aims at is to attract attention. He would rather be abused than not spoken about at all. He has noticed the fact that a plain, modest, hard-working man, doing his duty and serving humanity, attracts no more real attention than a thermometer on a balmy day. It is a sad commentary on the world that bow legs attract more attention than great virtues, and that a red nose causes more comment than a blameless life."

"A surgeon is like a postage stamp. He is useless when stuck on himself. A vain surgeon is like a milking stool; of no use except when sat upon. I don't see how any real surgeon can be vain. He is too often near to the inscrutable mystery of death—he sees too often the weaknesses of men—he too often stands at cross roads of judgment, knows that one way is the wrong way, but finds no sign to mark it—he too often has to reproach himself for mistakes—he too often sees calamity tread on the heels of calamity—he too often laments, impotent to save and watches 'Beauty and anguish walking hand and hand, the downward way to death'—he knows too well that Sophocles spoke the truth when he said:

The power of learning may a while prevail,
A time prolong a mortal's fleeting breath,
But useless all her arts are to avail
To conquer Fate or check the hand of Death.

"I don't see how any surgeon can be vain any more than I can see how an astronomer could be vain—an astronomer who peers into

the depths of infinite space which the hand of Omnipotence has strewn thick with star dust."

"Real success comes only from persistent hard work. No lily handed child of ease is entitled to it or can have it. Its insignia do not come from the general public but are conferred by the profession itself. Any temperament which keeps a man from sticking at it forbids success. Mere episodes of busy idleness do not constitute work. The loafer is a failure. To loaf in front of a church is just the same as to loaf in front of a saloon. One may loaf in a library, a laboratory, a hospital, as well as on a street corner, in a bar room, or at an afternoon tea. Indolence sterilizes the mind, but work will not create genius. It is an infinitely rare gift to dream the fairy tales of science. Genius alone dreams them, but even genius must work to make them real. I believe that real success can come only from work, but I know that even the hardest work may not command it. 'Tis not in mortals to command success.' Some work wrong and fail. Some work right and fail. Some work but fail 'until they grasp the skirt of happy chance,' by which they are dragged to the openings they lacked and the opportunities they despaired of obtaining. No man could dive for pearls on a mountain; no man could become an astronomer in a cave, and it may be impossible to create opportunity."

ACCEPTANCE OF RESPONSIBILITY

Only an analytical, understanding, philosophical, God-fearing mind could give voice to such reasoning. Only a man whose mind and heart strings, duty and cares have been rendered responsive to burden and responsibility could have laid bare his soul as follows:

"A surgeon's life is a hard one. It is a life of endless strain. During most of the hours of every day his faculties are keyed up tense almost to the breaking point, and physical tire goes hand in hand with mental exhaustion. He must carry and carry naturally the heaviest responsibilities. No matter how tired he is, his faculties must be alert, his judgment clear, his will inflexible, his knowledge accurate and instantaneously accessible for transmission into action. He must be calm, no matter what the clamor, the peril, the perplexity. Of course he will worry about his patients. Every conscientious man must do so. A man who doesn't worry at all doesn't care a whole lot. I should not want a man who did not care a whole lot operating upon me or mine. Perhaps worry is a device of nature to make us try to do our very best. If we knew we should not worry, we might be tempted at times to be careless. If a surgeon analyzes his worry he can get a line on what sort of man he is himself. If he worries only because he fears he may be sued, may lose

a bill or may hurt his reputation, then with him the voice of conscience is the fear of getting caught. If he worries because of the poor patient and the credit of surgery, then he is really a conscientious man. He must expect much harsh and unjust criticism and when he is the victim of it all he can do is follow Joseph Pancoast's advice and make his shoulders broad enough to bear the burden. A surgeon must learn thorough self surrender and all his life must wear the iron yoke of duty."

"Yes! the life of a surgeon is toilsome, responsible and anxious. It is a life of stress and strain. It is small wonder that surgeons as a class are not long lived. Pneumonia, angina pectoris, Bright's disease, vascular disease are the commonest agents of dissolution. The life is full of tragedy. Sometimes it seems as though a malign destiny were intervening in our affairs."

"The days of waiting for practice are very hard and very dangerous. Those days may make a man or mar him. The same wind which blows out the penny dip urges the flames of the forest fire. Those days go far in determining what sort of a man he is and is to be. During them he should study ceaselessly, learn to work, to observe, to think, and to teach himself. He should ponder deeply and often on the responsibilities and the duties of his calling. Thus he should become a real man, an individual, a man with genuine ideas, definite beliefs, established principles and high ideals. Thus he should avoid being a mere mimic and echo."

"There is grave danger in those waiting hours, those dark hours of poverty and nonrecognition. A sensitive soul will shrink, falter and probably fail. Brooding discontent is apt to dominate, and it is a deadly peril. Jealousy may spring up, envy may attain rank luxuriance, bitterness may grow, selfishness, avarice, disloyalty, mental dishonesty may be planted. Low ideals are ever knocking for admission. From them come admiration for despicable things, desires for unworthy objects and improper professional conduct."

The frequency with which he repeats himself is striking, but the explanation is freely given in a footnote in the Papers and Speeches of DaCosta: "I quote myself at times. Such quotations may mean scantiness of mental resources, but may also be due to profound conviction. If one believes he must preach and repeat. The great Carlyle did so often, surely an insect may."

His tribute to man's research and the enormous number of things yet to be discovered are shown in his frequent repeated expression "The first few hesitating words of truth have, as yet, but scarce been lisped by the baby lips of Science," as well as his profound reverence is illustrated and thoroughly impressed on his

own mind, for he repeatedly speaks of "the depths of infinite space which the hand of Omnipotence has strewn thick with star dust."

No greater tribute could have been paid to a man than was given to DaCosta by Francis T. Stewart before a class in the surgical amphitheater in Jefferson Medical College of Philadelphia in 1917 when, in describing a rare and unusual case, he said "I wished to know something about this condition, I asked Professor DaCosta, and as was always the case, I received concise information—he told me who first described the condition and when; who and where the first operation was performed; the present status of the operation with the improvements."

A RETENTIVE MEMORY

During his last illness in the hospital a doctor in visiting him spoke of Dickens, and DaCosta quoted at length from *Dombey and Son*. The doctor went home and looked up the quotation in the book. As near as he could tell the quotation had consumed several pages of the book, word for word. This visitor was not satisfied and made it a point to call on this ill surgeon a few days later and brought up the subject of *Dombey and Son*, asking when he had read it. DaCosta said "I have not had that book in my hands for over twenty-five years."

He was the same with all medical subjects. He knew; he possessed knowledge. It was an inspiration to be in his presence. His lectures were a mastery of diction and information; he never sidestepped a point but was emphatic, concise and dogmatic in his views. One was never in any doubt either of his knowledge, his authority or his position on any matter or subject. As a friend he was superb; as a foe, implacable. Who that ever heard could forget the lecture on appendicitis: "Appendicitis is inflammation of the vermiform appendix; it is characterized by abdominal pain, which is often general, colicky in nature but sooner or later localizes in the right iliac fossa; there is often nausea and vomiting, there may or may not be constipation; there is usually fever and leukocytosis; there is localized tenderness and rigidity, headache may be present, but abdominal pain which has been preceded by headache is not appendicitis."

ATTITUDE TOWARD WOMEN

His "pet peeve" however, seems to have been women. He observes that Dickens's description of Sairey Camp and Betsy Prig portrayed clearly the nurse as she was about seventy-five years ago, "A hideous affront to intelligence and an insult to humanity, often dirty, generally unscrupulous, usually drunk and always ignorant." The same often applied to the early

nurse in The Old Blockley. However, the modern nurse was characterized as the antithesis of the oldtime hireling—well educated, clean, intelligent, refined, conscientious, she is truly the right hand of the physician. DaCosta read all the works of Mary Roberts Rinehart, of whom he was very fond, but in an article entitled *Suicide*, read before the American Philosophical Society, he waxes eloquent regarding women: "Of late there has arisen a disposition to bring women into the forum to combat with men while the home takes care of itself. Those possessed of this disposition repudiate anatomy, spurn physiology, and disregard religion, history and common sense. Woman is not competent in man's work, she is inefficient, she loses at least twice as much time from sickness and she breaks down under sudden strains of overwork or difficulty."

"When she works as a man she must put aside not only many charms and prejudices but womanly things in general, and among those things she must put aside are healthy babies, the home and the rearing of children, and God Almighty constructed her bodily to bear children and mentally to rear them. Such women may have children but the job is usually very ill done. She cannot do properly what she was built to do. . . . If a woman invades man's callings she will pay a dreadful penalty in insanity, suicide, and in the delivery of her progeny; she will wreck the chief hope of the civilization, the clean, decent, happy home. If she works as a man she will be treated as a man and will be subjected as is a man to a multitude of irritations, depressions and worries from which she is now free. A woman's real profession is matrimony and she often makes a bad failure even in her natural profession. To make a success of this will require all her ability and energy, tact and self sacrifice. She had best leave man's affairs to man." "The blatant and militant suffragette is well along on the highway of degeneration."

A man cannot write concerning his chosen profession or teach the subject nearest his heart without weaving his own soul into it. The many editions of DaCosta's *Surgery*, his many scientific articles, his marvelous lectures, the honors and degrees heaped on him are too well known to be repeated or can well be imagined. He often settled arguments in a peculiar though philosophical manner. On one occasion when at a surgical convocation two groups of surgeons were presenting cholecystectomy versus cholecystotomy, and when he was called on to open the discussion, DaCosta's nimble mind offered this. "I have listened to the distinguished surgeons from the East argue for

cholecystotomy; I have listened to the equally distinguished gentlemen from the West argue for cholecystectomy. Gentlemen, it is all a matter of experience, but experience doesn't prove a thing or there would not be such a thing in the world as bigamy."

RADICAL AND CONSERVATIVE SURGEONS

In contrasting the two varieties of surgeons, he wove his ideals, his hates, his hopes, his detestations, his tolerance, his intolerance, his happiness, his sorrows and his knowledge into a glorious landscape of words and phrases, where the dead trees only served to accentuate the glory of the living verdure; where the mountain tops of knowledge were rendered the higher by contrast above the abysmal valleys of ignorance; where the clouds of doubt and dismay modified the soft rosy tints of the daybreak of science and the rising sun of achievement.

"Gradually, as a man becomes a surgeon, he tends toward one of the two fundamental groups into which all surgeons are divisible. The mental tendencies of an individual determine to which group their possessor or victim belongs. Each type has its strengths and its weaknesses. Each may be potent for good or active for evil. The ideal surgeon has not as yet been born. He would possess the strengths of both types and the weaknesses of neither. He would have wisdom as well as knowledge—tact as well as skill—confident hope as well as cautious doubt. His hand, like that of Joseph Pancoast, would be as light as floating perfume—his eye as quick as a flashing sunbeam—his heart as broad as humanity—his soul as sweet as the waters of Lebanon."

"One fundamental class is the conservative, the other is the radical. The conservative is often a most valuable factor in surgery. He is a brake on the wheel and often stops the dashing automobile of progress when on a joy ride from upsetting in the ditch of folly. He smothers the torch of the fantastic, snatches the mask from pretense and punctures the hot air balloon of egotism. He studies the past and reveres it, likes to penetrate its cities and its silences, to repeople its mouldering ruins, and to worship at its shattered shrines, and, in the words of Macaulay, looks back upon some Golden Age that has had no existence outside of his own mind. He attaches an exaggerated importance to books, and minimizes the value of new methods of communicating ideas. He has a great respect for authorities, and would rather 'sin with Pope than shine with Pye.' He is prone to write ponderous treatises, each of which has a name so complicated that it sounds like a sobriety test. He is apt to regard present day claims through the dim sublimation of the foggy and remote. He regards each so-called 'new'

thing as a wrong basely done to the established order and agrees with Solomon that there is no new thing. He is very doubtful of the possibility of reforming anything or anybody. He follows custom even when it is unreasonable or actually absurd. His headlight, like the light of the glow worm, is on the wrong end. He progresses, but in a circle, like the hands of a clock. He is not the active minded man behind the gun, but the slow and often dull man behind the times. His ideas are from a reservoir and not from a spring. Such conservatism may be temperamental opposition to change, may be a mask for incapacity, or an excuse for laziness. He may block or drag back the auto of progress even when it is moving surely, in the right direction and on the right road. He is apt to be a pessimist—seeing the thorns and not the roses—seeing the hole in the doughnut, but not the doughnut.

"The best and most useful conservative is one who has the radicalism of youth and inexperience corrected by age and experience. He is cautious of accepting new things, but can be brought to believe them. He leans to traditional notions, but may be divorced from them after showing him the conduct of the correspondent Error. He will make no successes which will shake the world, but he will make few irremediable blunders. In trying conscientiously to reach a decision, he will often be plunged neck deep in a barrel of quandary. He will be a careful and successful but not a brilliant or notably rapid operator. He will probably be respected, learned, and prosperous."

"A conservative man, when he looks through the spectacles of conservatism, will see common things with the greatest clearness and will come to know them with absolute certainty, but he will be unable to recognize the Good Fairy coming in the loathsome disguise of a Discovery."

"Our most splendid triumphs, our worst mistakes, and our saddest failures come from the radical mind. It is a spring and not a reservoir. It is a voice and not an echo. In the radical group are the original thinkers, the investigators, the discoverers, the combative spirits who 'fight like raging devils for conciliation and hate each other for the love of God.' The real radical believes a new statement because it is new, and doubts an old view because it is old. He blazes the way for lesser minds but is always in danger of being lost in the jungle. His feet may be in the muck heap, but his head is among the stars of space. He is a dreamer of dreams. If he were to lose a leg, he would congratulate himself that he now had but one foot to keep warm. He habitually ignores the reasonably probable and revels in the doubtfully positive. His ideals are broad, expansive, on a great scale. He is ever seeking to make converts. He has

an utter contempt for authority. He jumps to conclusions and may make the champion long distance leap from the frying pan into the fire. He has fierce controversies, devises operations, founds hypotheses, launches theories, discovers diseases, and dazzles all who know him by brilliant flights and amazing activities. As an operator he is brilliant, relying upon skill more than judgment, taking desperate chances, and skimming almost gaily within a hair's breadth of the deadliest catastrophes. He needs to have ever on duty by his side a peculiarly attentive guardian angel. He is never moderate, in fact, he scorns moderation. He is invariably convinced that he is always right. He will not brook contradiction and regards opponents as instigated by the worst possible motives. His knife may cut for good or ill. He obtains wonderful successes and makes dreadful mistakes. He is often a copious and hasty writer, rather prone to recording things as certain long before they are proved. He loudly claims credit he thinks his due. He rides the Rosinante of a hobby as though it were a splendid charger. He often fails to reach his goal and, like a squirrel in a cage, rises only to fall.

"The best type of the radical makes the real progress of humanity. Such a great man is a most attractive personality. He may die poor through adhering to some ideal."

WILLINGNESS TO RECOGNIZE OTHERS

There is another peculiar claim to greatness, rare, but possessed by this man, namely his willingness to pay tribute to ability and accomplishment of others. The baseness of ingratitude shook him deeply, for he said "I am impressed by ingratitude, the ingratitude of patients and in assistants whom I have helped and, believe me, I have experienced both." A veritable anguish is in the heart of one who will say "The death of a patient after an operation is always hard to bear; it is particularly hard to bear if unexpected. Did any one of you ever have a patient die from an anesthetic? I did. It was horrible. Such an event will shake the strongest man."

He accepted the illness which caused his death as the true leader he was, for a man to be a leader must be primarily a soldier, accepting a soldier's life, a soldier's sacrifice, a soldier's glory and a soldier's death. He chose early in life a variable star to follow—the twin star of service and duty. He followed it constantly, consistently, energetically and courageously. He has joined the immortals, but he has immortalized himself in American surgery and in the hearts and minds of all who were fortunate enough to bask in the radiance of his knowledge and glory.

1711 Green Street.

Teaching Surgery

W. T. COUGHLIN, M.D.
ST. LOUIS

Those of us who are old enough to remember the condition of our hospitals and the character of the surgery practiced in them, even in the first decade of this century, alone are able to appreciate properly the changes that have occurred and the progress that has been made. The surgical profession of this country for the past twenty-five years has continuously and strongly emphasized the idea of improvement of the care of the surgical patient.

The most certain indication of a better and better outlook for surgery is this: The medical schools are going to teach it as a specialty; graduate courses for the study of surgery in medical schools are every year becoming more and more sought after by those qualified, and the number of graduates who have already served as interns and who are willing to spend the additional time and money in order to qualify themselves to meet the requirements of the American Board is gratifying. If the rule that "a man must learn to do by doing" were literally true, then no one could ever learn to practice until after he had practiced. But a man can become qualified to perform surgical operations without "slaying his thousands." He may do that by becoming an assistant to some well qualified surgeon who is also qualified to teach him (such are scarce); or he may enter on a period of special training in medical school and hospital. As to the length of time required, there may be a difference of opinion. Those who have observed are well aware of the fact that there are some men who require but little teaching; those, at the end of the first year, are better qualified than some of the others will ever be, no matter how long they are trained. The period of training under supervision should be at least three years in actual work with patients after at least two spent in reviewing the fundamentals, especially anatomy, physiology and pathology.

All surgeons know that it takes something more than a bright mind and strong desire to make a successful surgeon. Many an extraordinarily bright and well trained man has never been able actually to "make it go" successfully either in institutional or in private practice. There must be a natural aptitude for it.

A man taking graduate work in surgery should not be trained like a child. The opportunity ought to be afforded him to learn surgery, but that he should be "supervised" is to me ridiculous. Some of those having a good

deal to do with the graduate schools seem to think that surgery can be learned like Greek or Latin or history—so many hours, so many credits. Very bad is the idea that much more "credit" should be accorded a man for what is called "research" than for excelling as diagnostician, pathologist and practical surgeon. However, in the main it must be acknowledged that those engaged in teaching surgery are those who know it best and do it best.

USE OF RESEARCH

Research is, of course, most valuable, but a genius in research might be a failure as a surgeon. The best surgeons are those who know enough about research to enable them to increase their store of knowledge by intelligent experiments on the lower animals when, as and if the spirit moves them. It hasn't been so long since degrees in surgery were given for "original investigative work" extending over a period of six months to a year! Surgery cannot be learned in this way.

TRAINING GIVEN AT ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE

I wish to outline what we have been doing in our medical school and I should like to receive criticism, because I know, of course, that our plan is not perfect. The question is whether we shall be able to devise a better plan; by receiving criticism we shall at least learn some things not to do.

We began with a two year course twelve years ago, which has now been lengthened to four. A candidate must have creditably completed a rotating internship of one year. He begins his course in the department of pathology, where he must remain one year, applying himself to general pathology and to surgical pathology. If his work has been satisfactory to the head of the department of pathology, he enters his first year's hospital service.

In his first year's hospital service only two thirds of his time is given to the hospital, one third being spent in the anatomy, surgical pathology and experimental departments. He does no major operations on the human body during this year but he is first assistant in all but the most formidable operations; in these he must be second assistant. He is permitted to use the experimental laboratory and is furnished with materials. He experiments in acquiring technic. He is direct supervisor of the work of the intern.

His second year more or less repeats the first with the exception that this year, on pre-

Read before the St. Louis Surgical Society, Jan. 9, 1940.
Dr. Coughlin, who was professor of surgery and director of the surgery department of St. Louis University School of Medicine, died May 22, 1940.

senting a certificate of proficiency from the director of animal surgery, he is allowed to perform major operations on the human body if assisted by one of professorial rank. He may act as first assistant in any major case. In the most serious, such as operations on the brain, lung or stomach, he must be first assistant. In this year we use him during his school service as an instructor in anatomy and surgical pathology. He has the laboratory of technic at his disposal and must perfect himself in the technic of each major procedure before he will be permitted to perform it on a patient, even though assisted by the professor. We use him as an instructor for interns and for nurses. By the middle of this year he shall have completed a clinical study of his own choice, begun in his first month of hospital service and based on material that has passed through the hospital or outpatient department.

His fourth year of preparation is almost equally divided between hospital and school. He fixes his own schedule. He is given complete charge of four beds. It is up to him to keep the cases moving. His work is under the immediate supervision of the chief. He is, on request, entitled to the assistance of any one of professorial rank. He must not accept assistance of any one less than senior intern. In the last half of his service he does some animal experimentation and must present, at the end of his service, a thesis based thereon. His laboratory materials are furnished him without cost. We use him as a service supervisor, intern and extern instructor and, in the school, as demonstrator in anatomy and surgical pathology. He is expected to be able to pass a practical examination in anatomy, physiology, pathology and surgery at the end of the course.

We cannot yet know whether this is the best way to train surgeons. It will take fifteen or twenty years to decide the question. My opinion is that not all those who get such an opportunity will become surgeons, and many will yet become men of renown in surgery who will never have enjoyed such opportunities to learn it.

COMMENT

Has our method any advantages over the established method—that of learning through a long assistantship? Certainly the best way to qualify in the purely clinical aspects is the long period of assistantship with a master surgeon. But, as has been said before, master surgeons are rare. There are so many doing surgery in this country that the clinical material which falls to one man is not as abundant as formerly. Although there is greater need for a greater number of better qualified men, yet few can become master surgeons. These men whom we are turning out would make excellent associates

for well qualified surgeons until they become a few years older. These men, after all this training, are all under 30 years of age—some no more than 26. Surely this is too early an age for the acquisition of a surgical practice. Could it be better done in some other way?

Before he ever comes to learn surgery is the time for the prospective surgeon to learn medicine and people; he could do that in no better way than by going out into general practice at the end of his junior internship. Let him spend at least five years in this and then let him seek a course in general surgery, something like what I have outlined. It would require a certain "calling" in the candidate to go through with such a "proving." He would certainly have the necessary fortitude, and there are times in every surgeon's life when fortitude is a prize. Any young man who, having once established himself in private practice, is willing to "throw it all up" for an opportunity to study surgery for four years surely is willing to make a large sacrifice, and I believe that he would become a credit to his profession. The contention is that such a plan would take too long. Well, the young surgeon gets pretty well over being young before he gets much private surgical practice. He is not expected to get much practice of his own before he is 40. As it is, unless he is fortunate, I fear he must be often hungry and many times find his virtue sorely strained. No surgeon can be much credit to surgery these days unless he confines his attention to surgery. No one will enter surgery from now on except by the door of special training.

Beginning to Practice.—When you enter a new community, appearance is important. You do not have to have the most expensive clothes but what you wear can look well on you. Your car does not have to be new, but it can be respectable looking. Above all, cleanliness will make or lose a practice quicker than almost anything. After you have been out a few years, check yourself with your confrère as to whether you are keeping up to date. Have you attended meetings and read your medical journals? . . . As early as possible, become a member of your county and state society and meet with your fellow practitioners. Being charitable to the other doctor in your community is most important. . . . If you disagree with the other man's opinion, regardless of how bad his judgment has been, a kind interpretation of the case will make all happier, including the patient. Whenever possible, associate with men you have to look up to. This thought applies to business men as well as men in the profession. They are stimulating and will give you a subconscious lift. In your early practice associate yourself with dispensary services and charitable enterprises. It not only improves your knowledge but allows you to rub elbows with many people of value to you throughout your professional career. Always treat those in work associated with medical practice with kindness and respect. Although you will see doctors who will be unkind to nurses when they can't talk back, remember they have been taught to look up to you. See that they are able to.—Sproule, Ralph P.: *A Doctor Speaks to Students*, *Marquette M. Rev.* 5:1 (Nov.) 1940.

Digests and Reviews

GUY'S STUDENTS PASS EMERGENCY TEST

Slightly condensed from Guy's Hospital Gazette, Sept. 21, 1940.

Guy's Hospital has now been subjected to the effects of real modern warfare. The enemy has seen fit to indulge in indiscriminate bombing raids over the London area, and as a result we have received our share of casualties. On Saturday, September 7, in the late afternoon, a series of fires was started following an intensive air raid; using these fires as beacons, the raiders returned throughout the night to attack their military objectives or anything else in the very approximate neighborhood.

From the start of this offensive, a steady stream of casualties began to arrive at the Memorial Gates of Guy's Hospital. What we had organized and prepared for in the previous months had suddenly come to pass. Almost all of the patients were suffering from shock, a shock that was not only traumatic but also mental, for not a few of them had seen their relatives and friends fall victims to this German wretchedness.

Both medical and surgical staffs worked in complete harmony under the constant supervision of our deputy superintendent. The immediate problem in the majority of cases was the adequate administration of resuscitation. The architectural deficiencies of our buildings were easily overcome by the stable cooperation of the stretcher bearers, who worked ceaselessly and without complaint. This is not the time for a description of cases, but one cannot help remarking on the almost dramatic recovery of seemingly lifeless casualties after a vigorous regimen of resuscitation had been instituted. Many of these patients who had suffered a multiplicity of perforating wounds of the chest and abdomen together with head injuries and burns were removed to the operating room within a few hours of admission; there our surgeons operated on them, applying their tireless skill without effort and with admirable patience until their job was finished.

To avoid congestion of the wards by the accumulation of patients, a system of evacuation to base hospitals was started at once. Just as soon as emergency treatment had been applied and the patients had sufficiently recovered, they were comfortably accommodated in a stretcher bus, appropriate care being taken of the injuries so that patients did not suffer by transport. In spite of many of these operations taking place at night under constant exposure to bombs and shrapnel, there is not a single report of any patient having suffered adversely from the journey.

The performance of students and nurses throughout the entire procedure has been one of merit and a tribute to themselves and to Guy's Hospital. There was not the slightest suggestion of hysteria or fright among any of them, but, instead, each worked with a cool efficiency, applying his own intelligence to what had to be done instead of stupidly standing about waiting for orders. When there was work to be done there was always an abundance of available personnel ready on the spot; in the intervals between action, each person sought out a safe underground room and curled up in a well deserved quiet sleep.

Many months ago the student body was released from the Emergency Medical Service. At the time there was a good deal of speculation as to the reaction of the students, especially with regard to what might be expected of them when their services were really required. That question has now been answered; without thought to their personal safety, without bitterness or even a grumble, sleepless and fatigued as they were, they piled into each new task with a vigor that did them credit.

THE ANATOMIST IN MEDICAL EDUCATION

Abridgment of a lecture by Lewis H. Weed, professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, delivered at Washington University School of Medicine, St. Louis, May 17, 1939, and published in the Journal of the Association of American Medical Colleges, September 1939.

I propose to discuss the field of anatomy in its broad relation to medical education. From the derivation of the word, anatomy would seem to be restricted to the cutting apart of finished total structures, but the subject matter studied by anatomists today extends far beyond the body structure of man and animals. To the time honored method of investigation through dissection with scalpel, probe, scissors and forceps, the anatomist has added to his tools of trade the microscope and microtome, the incubator and culture slide, the caliper and measuring rod, the kymograph and induction coil, even the spectroscope and colorimeter. Anatomy has evolved into a mother science which embraces certain well defined subdivisions—gross human anatomy, comparative anatomy, histology and cytology, embryology, neuro-anatomy and physiological anthropology.

Today a broadly extending academic discipline, this anatomy of medical schools has come to be one of the major biologic sciences that have to do with life processes as these affect the structure and to a lesser extent the function of vertebrates. The anatomist

remembers the position of his subject in the training of physicians up to a century or so ago, when practically the entire basic instruction of the young physician was centered in the dissecting table. The body of biologic fact was then all too small; yet out of anatomy grew physiology. With the development of the autopsy technic, gross morbid anatomy came from the dissecting table and soon assumed adolescence and adulthood as a separate university discipline.

EVOLUTIONARY CHANGES

The discovery of cells through the use of the compound microscope added its share of complications to the simple structure of medical education. While the anatomist was learning to use the microscope, the pathologist likewise was employing the same means toward unfolding the disturbances of structure caused by disease. Then, in the fourth quarter of the last century, medicine was advanced by the discovery of the relation of certain bacteria to disease, and medical education processes again had to accommodate themselves to a new subject in teaching. At the same time chemistry began to make its claims on the medical curriculum and, with the development of its biologic aspects, still another major discipline found its place in the required work of the ever suffering medical student. Almost simultaneously the study of materia medica became invigorated and altered through the introduction of chemical and physiologic approaches and a true pharmacology assembled a new mass of information, dislocating much of the old but retaining some of its classic learning. Even with these inroads into the curriculum there was plenty of time for all the required instruction in the four year course offered by the best American medical schools at the beginning of the century.

But how different it is today regarding the demand for required hours in the medical curriculum! We are still giving—and I believe properly—the degree of doctor of medicine at the end of the classic four year period. But, since the turn of the century, the total body of fact in medicine has increased enormously. Clinical medicine is no longer based entirely on pathology. During the past forty years chemistry, physics and physiology have contributed their full share to medical diagnosis, therapy and prognosis. The study of disease has broadened, to become rather paradoxically an investigation of the disturbances of physiology; of parasitism by bacteria, viruses, fungi and protozoan forms; of the biology of new growths. Alongside this development of internal medicine, the subdivisions of surgery have all undergone phenomenal growth.

These evolutionary changes have all occurred within subjects included in the medical course of fifty years ago. Yet other developments have

taken place in recent years, and the overcrowded curriculum of medical teaching is being pressed to include these also. Prominent in this group of new subjects is that of preventive medicine. And closely allied to this aspect there has come realization that medicine does not cease with determination of the diagnosis and therapy: that there are social, environmental, economic factors in disease which must be included in the summary of the patient as a sick individual. Then too industrial medicine, forensic medicine and medical genetics likewise have their many advocates; and the end is not yet in sight. Nor do we wish the end to come: we live in a field of advancing medicine and I pray that this pressure, embarrassing as it is to medical deans and curriculum committees, will never cease.

PURPOSE OF THE MEDICAL SCHOOL

What, then, should be the primary aim of the faculties of medicine which are responsible for the arrangement of the course of study leading to the degree of doctor of medicine in four years? The chief purpose of the medical school is to train physicians in the best possible way. Just what the faculty of medicine does in its course of instruction is in the final analysis determined by local opportunities, by local facilities, by the quality of the faculty and by the extent of financial support. The result is, in my opinion, most desirable, as it ultimately produces medical schools of widely diverging character. The aim of all these schools remains essentially the same—to train the best type of physician. If one adopts the contention that the chief aim of medical education should be the establishment of an attitude of mind toward the study of disease, the arrangement of the course of study and the general disposition of required and optional work become matters of relative indifference. The pattern of the curriculum is of secondary importance.

With such a concept of curricular patterns, we can view with calmness the constant reduction of required hours in courses like those in anatomy. The decrease in time allotted to anatomy seems the more striking as for many years anatomy formed almost the entire basis of preclinical instruction. For many generations anatomy had no real competitors in the struggle for the student's time.

SCOPE OF FOUR YEAR MEDICAL COURSE

Everywhere throughout medical schools today there is realization that in any of the prescribed divisions of instruction the student has time merely for an initial survey of the subject matter of that branch of medical knowledge. The fund of information is too large in every one of these subjects: the student can at best obtain merely the biologic philosophy of the subject, hardly the pertinent details. He learns in a preliminary way the manipulative procedures

employed in the field for the acquisition of knowledge, but the acquirement of technical skills is postponed in this educational process to the intern-resident years or to the years as laboratory assistant. Our four year medical course, therefore, becomes a preliminary canter across a wide and rugged field. The student acquires a general comprehension and a philosophy in each course rather than a great body of specific knowledge and a mastery of technical procedure.

The merit of this postponement of the acquirement of the technical proficiencies until the postgraduate years is that it has permitted medical teachers to devote their energies largely to presentation of biologic points of view rather than to insistence on technics. Here medicine has been more fortunate, or wise, than dentistry. For in American dentistry we are confronted with an art standing supreme in its international field as a health service. Dentistry is today a superb artistry, but only relatively few dental practitioners or teachers are aware of the full biologic implications of disease of the teeth and jaws. The dental schools of America have insisted that their students acquire in the four year curriculum all of the technical proficiency needed for immediate practice. The dental schools provide biologic courses in the preclinical medical sciences for roughly one and one half years of the four year course; then, in spite of sporadic efforts at reform, the school superimposes two and one half years of the most rigid technical discipline. No wonder that the scientific interests of the average dental student in the biologic and medical aspects of his great subject do not survive. The number of dental teachers who still maintain the spirit of investigative curiosity, except as to technical method, is woefully small. The result of the development of superb technics in dentistry has been a pulling away from medicine: dentistry has become too largely a restorative and reparative art. It has produced a technical perfection which is not being applied, and cannot be applied, to the whole population. Technical dentistry, therefore, has arrived in a blind alley: it can liberate itself as a health agency only by developing a biologic point of view and a biologic body of knowledge. To do this the dental school should emphasize the underlying biologic sciences and relegate technical training, except as to the theory of procedure, to postgraduate years. It would do well to follow medicine in its educational program.

MEDICINE A BIOLOGIC SCIENCE

Medicine is rapidly becoming more and more of a biologic science. The practice of medicine is still essentially an art, but alongside this art an appreciable body of scientific fact in human and mammalian biology is continuing rapidly to accumulate. As biologic information relating to

man is in the future assembled through the efforts of geneticists, biometrists, anthropologists, anatomists, physiologists, chemists and others, medicine will stand forth not only as a curative and preventive art but as a great division of human biology.

And in this future medicine the anatomist will retain the same place in medical education that he now occupies. The anatomist will continue to teach human morphology in its widest sense. Unquestionably, it will be a larger and more soundly based subject than the gross and microscopic anatomy of today; but it will still be aimed at the disclosure of man's structure.

In the future schools of medicine I look forward to the subjugation of technics and arts in medicine as a means toward an end; therapy and prevention will rest on a fundament of sound biologic information. In the future there will still be employment for the anatomist in medical education, still an opportunity for the anatomist to supervise the student's work on human structure, still the rare and priceless privilege for the anatomist to cultivate and encourage an intellectual curiosity in the medical student, and still problems requiring attack by the anatomist.

ANATOMY AND ITS SUBDIVISIONS

The field of future endeavor looms larger and more significant than it has in the past. While it may, in some laboratories, be unfashionable momentarily to work on the problems of gross anatomy, this subdivision of the science still presents a multitude of questions of fundamental moment. With new points of view, anatomists are returning to the great subject of variability in human structures to the study of racial anatomy.

But what of the other subdivisions of anatomy in the future? The nervous system will continue to demand the concentrated attention of anatomists. Correlational studies, relating structure to function, will probably still offer the best chance of profitable return. Various mammalian forms, representing special adaptations to functional needs in nature, afford splendid material for generations of earnest research. And possibly most fruitful of all will be the investigation of the anatomic and physiologic maturation of the nervous system.

The great field of endocrinology, in which stupendous progress has been achieved in recent years, will continue to attract the best efforts of anatomists. To the advance of the past twenty years the anatomist has contributed a large share, and it seems most likely that in cooperative endeavors with physiologists and biochemists the anatomist will continue to add an important factor in morphologic control. The potentialities of these phases of endocrine function are almost unexplored.

In embryology a tremendous opportunity lies ahead and we are just taking the first timid steps in an endeavor which a few years ago would have been impossible. The solution of the significant problems of implantation and early embryonic development will add a chapter to our knowledge of human growth. Today the field of chemical or physiologic embryology is opening up to new endeavors, and with the recently discovered weapon of radioactive chemical substances a wholly novel aspect of embryonic development and growth will be unfolded in a generation or two. Histology and cytology

are employing new means of attack on the chemical constitution of the cell. We have now the initial advances made by the methods of micro-incineration, of freezing drying fixation, of spectroscopic analysis, of quartz system spectrographic study with ultraviolet rays, and of the electron microscope.

It seems obvious that the anatomist has before him a great opportunity in research of prime importance to the understanding of structure. The anatomist has had a place in medical education; he will, I believe, continue to have one of the important roles in future medical education.

Comments

Dr. Nicholas Senn once said "A good surgeon is a good physician who operates."

In 1736 the first successful mastoid operation for suppurative disease was performed by Jean-Louis Petit (1674-1750). He was the foremost French surgeon of the early eighteenth century.

The first degree of doctor of medicine conferred on a woman in the United States was that received by Dr. Elizabeth Blackwell on Jan. 23, 1849, from the Geneva Medical Institution, affiliated with Hobart College, at Geneva, N. Y.

Dr. John B. Vernaglia, a surgeon at Medford, Mass., caught a tuna fish in Ipswich Bay, Mass., weighing 927 pounds, which is said to be a world's tuna fish record. The previous largest tuna fish, weighing 890 pounds, was caught by John Manning off Nova Scotia in 1939.

Since 1933 the number of women applicants to the freshman class of seventy-seven medical colleges in the United States had increased, the largest number being 689 in 1935, since which year there has been a gradual falling off in numbers. In 1939 the number of women applicants was 632, of whom 321, or 50.8 per cent, were accepted; in 1933, 62.3 per cent of the women were accepted.—Fred C. Zapffe, Secretary, Association of American Medical Colleges, Chicago.

Charles Robert Darwin, although an invalid for the rest of his life, labored for twenty years before publishing his great work "On the Origin of Species by Means of Natural Selection" (1859), perhaps the most wonderful piece of synthesis in the history of science. Darwin's extraordinary marshaling of facts, in evidence of the survival of the fittest by natural selection in the struggle for existence, had the same far-reaching influence on biologic speculation that the discoveries of Copernicus had on astronomy.—Fielding H. Garrison.

FOODS HIGHEST IN POTASSIUM

Bananas	Kohlrabi	Olives
Cabbage greens	Legumes	Paprika
Caviar	Lemons	Parsnips

DO YOU KNOW WHAT PHYSICIAN—

1. Was the first priest-physician of whom we have a record?

2. Was Ambassador from Great Britain to the United States?

3. By his discoveries in astronomy revolutionized science in general and established astronomy on a sound basis?

4. Invented a machine for unwinding the fiber of silk cocoons?

The answers are on page 1944

Correspondence

A SENIOR STUDENT VIEWS THE INTERNSHIP

To the Editor:—I should like to report the existence of a disease entity about which no literature has been written but which has existed since the birth of modern medical education. This disease is peculiar to medical students, is pandemic, beginning at the end of August (with the issuance of the "Educational Number" of THE JOURNAL) and lasting for an indefinite length of time, depending on two factors—"pull" and "resistance." Pathologically this is a disease of the psyche and runs a characteristic course. The onset is usually insidious, with prodromal symptoms of unexplained elation following third year final examinations in June. At the end of August, with the issuance of the aforementioned "Educational Number," the patient begins to feel overwhelmingly confused, undecided and unusually solicitous toward "friends" and professors. This is immediately followed by a period of undue overconfidence and grandiosity. During this period the individual closely resembles the schizophrenic, for he is continually building hospitals in his mind and living gloriously in them. On November 15, there is a sudden and marked state of depression, disorientation and confusion. This also lasts for an indefinite period of time, but sooner or later the individual returns to normal. However, there are certain sequelae which leave a definite impression on the individual's personality. Treatment, of course, is a satisfactory internship.

This brings me to the main thought of my letter, namely that procurement of internships is as bad as ever. This should not be so, for to me this matter is a simple one, revolving around two basic factors:

1. Hospitals want interns.
2. Students want internships.

However, there is a conflicting element in that some of the larger hospitals do not recognize the graduates of some of the less publicized schools. Therefore, when a student applies at these hospitals he is unmindful of this condition. With ignorant hope he wastes precious time which he could have used to better advantage by applying at a more sympathetic hospital. Consequently, I should like to submit this plan for your consideration. The plan is as follows:

1. Each hospital approved by the American Medical Association as found in your educational number is to receive each year on a definite date a list of approved grade A medical schools.
2. From this list each hospital is to pick a number of medical schools from the graduates of which it will entertain applications for internships.
3. These choices are to be sent to the American Medical Association, and this information is to be rearranged in such a manner that each school will know which hospitals will consider the applications of its students.
4. At the beginning of each school year each medical school will post a list of those hospitals which have expressed their willingness to receive applications from that particular school.
5. Appointments are to be made on November 1 by telegram, and each appointee is obligated to accept or refuse by telegram within twenty-four hours.

6. All hospitals that by the end of the following day still have vacancies are to report the number of vacancies to the American Medical Association.

7. A list of vacancies is to be compiled and sent to each medical school no later than November 15.

From this sketchy outline several advantages can be seen. First, and most important, the student who has no "pull" will not waste his time trying to get into a hospital where he has no chance at all. However, this does not prevent the student from trying to get into a hospital which is not on his school's list. Finally, the student after being rejected will now know which hospitals still have vacancies.

For those of us who are trying to obtain an internship this is a real problem. I submit this letter in good faith, with the hope that if this plan is not acceptable it will inspire other suggestions and further effort to remedy the present deplorable situation.

GEORGE SPECK, Washington, D. C.

FIRST SUCCESSFUL CESAREAN SECTION

To the Editor:—Under comments in The Student Section, bottom of page 1505 of the October 26 issue of THE JOURNAL, in regard to the operation by Dr. Richmond you state "The operation was done in Middletown, Ohio, in 1827. . . ."

The operation was performed just east of Cincinnati at Newtown, Ohio, on a servant of one of the early settlers of the Little Miami River Valley.

In 1912 the McDowell Medical Society of Cincinnati erected a monument in the memory of Dr. Richmond and of the first successful cesarean section in the United States, which he performed April 22, 1827.

JOHN T. CRONE JR., M.D., Milford, Ohio.

EDITORIAL NOTE.—According to Blanton in his "Medicine in Virginia in the Eighteenth Century," published by Garrett and Massie, Richmond, 1931, the first cesarean section in America was performed by Dr. Jesse Bennett on his own wife in a frontier settlement in the Shenandoah Valley in Virginia in 1794, which was thirty-three years earlier than that by Dr. John Lambert Richmond, to which Dr. Crone refers in his communication. Blanton writes: Mrs. Bennett's "labor was a difficult one owing to a contracted pelvis, and Dr. Alexander Humphreys of Staunton was called in consultation. The doctors tried forceps without success. Between the alternatives of craniotomy and cesarean section the patient chose the latter in spite of the opposition of Dr. Humphreys and his persistent refusal to perform such a dangerous operation. The case was urgent, and Jesse Bennett decided to operate himself. The patient, stretched on a crude plank table over two barrels, was put under the influence of a large dose of opium. Assisted only by two Negro women, the courageous frontier surgeon by one quick stroke of the knife laid open the abdomen and uterus and quickly delivered child and placenta. At this stage he delayed long enough to remove both ovaries. . . . The wounds were closed with a stout linen thread, and contrary to the expectation of every one present Mrs. Bennett was soon well and active. The child, a daughter, lived to be 77 years of age." It is

interesting to note that the oophorectomy performed on his wife by Dr. Bennett antedated Ephraim McDowell's famous operation on Mrs. Crawford by more than fifteen years. Dr. Bennett has not generally been given a place of honor in the medical history of

America, because he did not report his case in a medical journal. Dr. John Lambert Richmond reported his operation in Newtown, Hamilton County, Ohio, in February 1830 (*Western Journal of the Medical and Physical Sciences* 3:485).

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

First Aid Required of Minnesota Freshmen

The University of Minnesota Medical School, Minneapolis, has instituted a required course in first aid for freshman medical students. The one quarter course, consisting of fourteen lectures and six practical demonstrations, was instituted because it was felt that it was pertinent to the preparedness program in the event of an emergency. This is one of the first medical schools in the country to include such a course in the curriculum for freshmen.

Student on Orthopedic Program

Marshall R. Urist, a senior at Johns Hopkins University School of Medicine, represented undergraduate research at a meeting of the Robert Jones Orthopedic Club in Baltimore, November 7; his paper was entitled "Research in Calcification of Callus." There were papers also by Dr. Walter Dandy on "Intraspinal Causes of Back Pain" and by Dr. Warfield Firor on tetanus, and Dr. M. N. Smith-Petersen showed a movie on arthroplasty.

Vermont Lengthens the Senior Year

The office of the dean of the University of Vermont College of Medicine, Burlington, has announced that beginning next June 1 the teaching in the senior year of the medical college will be extended from thirty-two weeks to forty-four weeks.

Michigan Reduces Number of Prescribed Hours

Recognizing the value of independent thinking and self-conceived effort, the University of Michigan Medical School, Ann Arbor, has reduced the number of prescribed hours in the curriculum. The total number of hours required for didactic courses, clinics and laboratory sciences had become so great that students found no time for independent study and reflection. According to Dean Albert C. Furstenberg, medical training is not the accumulation of factual knowledge and information; it is the acquisition of understanding and powers of interpretation which gives the student a grasp of the practical problems.

Alpha Omega Alpha at Western Reserve

The following students of Western Reserve University School of Medicine, Cleveland, have been elected to Alpha Omega Alpha honorary medical society: Norma Anderson Beall, Daniel Anthony Brody, Janet Turreff Dingle, Gerald Tambling Kent, Aaron Paley, Leonard Michael Schuman, Joseph Selman and Lester Louis Williams.

Guest Speakers at Oklahoma

Dr. Alfred W. Adson, professor of neurosurgery at the Mayo Foundation, Rochester, Minn., addressed the entire student body of the University of Oklahoma School of Medicine, Oklahoma City, in October on "The Future of Medical Practice"; Dr. Elliott P. Joslin,

emeritus clinical professor of medicine, Harvard Medical School, Boston, on "Diabetes," and Dr. M. Edward Davis, associate professor of obstetrics and gynecology, University of Chicago School of Medicine, addressed the senior class on the use of stilbestrol. The addresses were delivered during the time of the meeting of the Oklahoma City Clinical Society, October 28-31.

New York University's Freshman Officers

The first year class at New York University College of Medicine, New York, has elected the following officers: president, John G. Murray of Brown University and Mount Vernon, N. Y.; vice president, Edward E. Banta of Dartmouth and Tenaflly, N. J.; treasurer, Sheldon Schwartz of Rensselaer Polytechnic Institute and Richmond Hill, L. I., N. Y.; secretary, Naomi de Sola Pool of Goucher College and New York; council representatives are Sidney A. Haber of Cornell and New York and Franklin Brundage of Cornell and Pelham Manor, N. Y.

Virginians Honor Yellow Fever Volunteer

John J. Moran was guest of honor at a dinner given by the faculty of the University of Virginia Department of Medicine, Charlottesville, October 23, at which the principal speaker was Brig. Gen. Jefferson R. Keane, U. S. Army, retired. Mr. Moran was one of twenty-three volunteers who contracted yellow fever in the famous experiments conducted in Cuba by the U. S. Army Yellow Fever Commission in 1900 and 1901, of which Major Walter Reed was chairman.

President Theodore Roosevelt transmitted to the Congress of the United States, Dec. 5, 1906, a memorandum addressed to him by Surgeon General O'Reilly, which listed the volunteers who had submitted to the yellow fever experiments in Cuba and had the following to say concerning Mr. Moran:

Conspicuous among them was John J. Moran, a civilian clerk employed at the headquarters of Gen. Fitzhugh Lee, at Quemados, who was one of the earliest volunteers for the second set of experiments, and whose action was dictated by the purest motives of altruism and self devotion. Mr. Moran disclaimed, before submitting to the experiments, any desire for reward and has never accepted any since, although he was offered the \$200 which the liberality of the military governor enabled the commission to give to each experimental patient, the members of the board excepted. Such was his modesty that he has made no effort, so far as known to this office, to make known his connection with these experiments and reap the credit which is so justly due him. Mr. Moran was a native of Ohio.

Utah Dissolves Medical Fraternities

The students of the University of Utah School of Medicine, Salt Lake City, recently voted to dissolve the medical fraternities and establish a medical student association. The first activity scheduled by the new association is to sponsor the annual medic-lawyer football game and the dinner dance which follows. John Bruce Balken '43 was elected president of the new organization; Norman S. Anderson '44, vice president, and Miss Denise T. Callister '43, secretary and treasurer.

Expenses at Tennessee

For Tennessee students, the expenses at the University of Tennessee College of Medicine, Memphis, amount to between \$225 and \$275 a quarter. The cost to students from other states is \$50 more. Tuition per quarter is \$70 for Tennessee students and \$120 for out of state students. A contingent deposit is maintained at \$15. Living expenses, supplies and books account for the remainder. Students are required to have a microscope, and in the second year a hemocytometer, hemoglobinometer, a blood lancet and a stethoscope.

Scholarship Awarded at Texas

Mr. Blocker H. Joslin '41 has been awarded the J. B. Kass Research Scholarship in Preventive Medicine at the University of Texas Faculty of Medicine, Galveston. The scholarship is awarded to a medical student selected by a committee comprising a faculty member, a representative of the student body nominated by the student's association and a representative of Dr. Kass. The purpose of this yearly scholarship is to encourage research in preventive medicine.

Growth of Louisiana's Library

The library of the Louisiana State University School of Medicine, New Orleans, is known as the Agramonte Memorial Library, in honor of Dr. Aristides Agramonte, who was a member of the U. S. Army Yellow Fever Commission, which conducted experiments in Cuba in 1900 that led to the discovery of the method of transmission of yellow fever. Dr. Agramonte was appointed professor of tropical medicine in 1931 at Louisiana State University School of Medicine but died shortly before the opening of school in that year. The Agramonte Memorial Library has just closed a successful year, during which a new workroom was added to the library, the stack space was doubled and a number of journal files were completed, bringing the total of complete files of journals in the library to seventy-eight. The library had at the close of the fiscal year 10,885 volumes, an increase of 20 per cent for the year. The circulation increased 7 per cent.

New A. O. A. Members at Emory

The following members of the senior class at Emory University School of Medicine, Atlanta, Ga., were elected last month to membership, based on scholarship, character, leadership and achievement, in the honorary fraternity Alpha Omega Alpha: William Rhett Craig, Walhalla, S. C.; Manne Adams, Sebring, Fla.; William Evans Goodyear, Emory University, Ga.; Charles Thornton Cowart, Danaldsville, Ga., and Cecil Glenn White, Tucapaw, S. C.

"Dad's Day" Banquet

More than 600 persons attended the banquet, October 12, at the State University of Iowa, Iowa City, in honor of the students' fathers. The toastmaster on this occasion was medical student John M. Rhodes '41, a member of Alpha Omega Alpha and of A. F. I., an honorary fraternity for outstanding senior students of all the colleges at the university.

College of Medical Evangelists

The juniors and seniors of the College of Medical Evangelists, Los Angeles, were addressed November 7 by Dr. Walter C. Alvarez of Rochester, Minn., on "Abdominal Pains," a lecture which, our correspondent writes, was essentially on the art of medicine. In attendance also were the interns of the Los Angeles

County Hospital, students of the University of Southern California School of Medicine and members of the faculty of these institutions.

The 298 students enrolled in the College of Medical Evangelists came from thirty-eight states, the District of Columbia, and the following foreign lands: Australia, Bermuda, British West Indies, Canada, Canal Zone, China, Dutch East Indies, England, Germany, Hawaii, Iceland, India, Iran, Iraq, Korea, Palestine, Peru, Philippine Islands, Puerto Rico, Scotland, South Africa, Switzerland, Trinidad and Turkey.

Harvard Students After Twenty-Five Years

A celebration was held in Boston in June by members of the class of 1915 of Harvard Medical School which was attended by forty-one of the eighty-four members of the class still living. Four men came to the celebration from California, two from Colorado and two from Missouri. The class met in the faculty room of Harvard Medical School to be addressed by A. Lawrence Lowell, president emeritus of Harvard University, Prof. Walter B. Cannon, Prof. Cecil K. Drinker and Dean Burwell. The next day the classmates visited the hospitals. Saturday afternoon the classmates and wives assembled for luncheon and class pictures, then motored to Harvard, Mass., to be entertained in the country home of one of their members. The class of 1915 contributed \$1,450, which was turned over to the dean for the use of the medical school.

Temple's Class Officers

John H. Kolmer was elected president of the class of 1943 and David P. Osborne president of the class of 1942 at the recent elections of the freshman and sophomore classes of Temple University School of Medicine, Philadelphia.

"DO YOU KNOW WHAT PHYSICIAN"

Following are answers to the questions appearing on page 1941:

1. Imhotep, who lived about 3,000 B. C. He was the most influential man in Egypt at that time. Imhotep gave such an impetus to medicine that about 700 years later it had become well organized. Temples of healing were built throughout Egypt in his honor. He was a real person and held the same place in Egyptian medicine that Aesculapius, a mythological character, held in Greek medicine. Imhotep was also the architect and builder of the first Egyptian pyramid.

2. Sir Auckland Campbell Geddes, who was professor of anatomy first at Edinburgh, then at the Royal College of Surgeons, Dublin, and afterward at McGill University, Montreal.

3. Nicholas Copernicus (1473-1543). Copernicus, a native of Poland, received his degree of doctor of medicine from the University of Cracow. After studying the motion of the heavenly bodies for years, he published in 1543 his treatise on the revolution of planets around the sun, giving proof that the sun was the center of the universe, rather than the earth.

4. Dr. Thomas H. Chivers (1809-1858). Dr. Chivers received his M.D. degree from Transylvania University (now the University of Kentucky) in 1830. He never practiced medicine as a means of livelihood, but throughout his life he practiced free of charge for those unable to pay. His chief interest was literature and his writings make several large volumes. There was a strong similarity between his style and that of Edgar Allan Poe. Dr. Chivers was awarded a prize at one of the fairs in his state for inventing a machine for unwinding the fiber of silk cocoons.

SURGICAL CORRECTION OF HORSESHOE KIDNEY

CHAIRMAN'S ADDRESS

FREDERIC E. B. FOLEY, M.D.

ST. PAUL

The anomaly horseshoe kidney, apart altogether from accompanying renal pathologic change, presents a clear-cut and definite clinical problem. It is the problem of what may be called horseshoe kidney disease as distinct from disease of the horseshoe kidney.

The literature abounds in reports of the occurrence of the anomaly horseshoe kidney and in descriptions of its morphology and autogenesis. There is an abundance of clinical reports dealing with disease of the horseshoe kidney. They recount occurrence of all the ordinary renal lesions such as hydronephrosis, pyonephrosis, stone, tuberculosis and neoplasm, found in association with this extraordinary form of kidney. Some of the reports speculate concerning the anomaly as an etiologic factor in occurrence of the associated lesion. In all but a few reports, to be mentioned in detail later, the anomaly has not been held directly responsible for the symptoms present and no attempt has been made to eliminate it as an etiologic factor by restoration of normal anatomic relationships. They are simply reported cases of common renal lesions occurring in an uncommon anomalous kidney. Such cases do not touch on the clinical problem of the anomaly itself—that is, the problem of relieving the painful and other symptoms caused by the anomaly and preventing or arresting pathologic changes that may insidiously accompany it.

A horseshoe kidney not affected by any significant pathologic change apart from the anomaly may be productive of symptoms demanding relief. With the exception of only a few reported cases, surgeons have failed to accord this relief and apparently have failed to contemplate the surgical problem of doing so. It will be shown by the personal cases here reported and by analysis of other cases reported in the literature that surgical correction of the anomaly by division of the isthmus and nephropexy on one or both sides is capable of restoring normal relationships and relieving the subjective symptoms that may be caused by the anomaly.

With the exception of twelve cases reported prior to 1930, when the present thesis had its inception, and six cases reported since then, all clinical reports have neglected this particular and very important phase of horseshoe kidney disease. This cannot be said of

Gutierrez's monograph "The Clinical Management of Horseshoe Kidney,"¹ published in 1934. Gutierrez originated the term "horseshoe kidney disease" to distinguish cases of the anomaly not associated with significant pathologic change from cases in which concomitant disease of the malformed kidney is present. It is a useful and descriptive term and should be retained.

Although not supported by the results of personal experience, Gutierrez concluded that horseshoe kidney per se without any accompanying renal lesion of significance is capable of causing subjective symptoms and that these should be amenable to relief through surgical restoration of normal relations—that is, operative division of the fused kidneys and their restoration to normal positions.

Prior to Gutierrez's publication in 1934 I had already embarked on the same thesis by another avenue—trial of the operation. In 1935 a preliminary report² described the early results of this operation in five cases in which there was no significant pathologic change apart from some degree of the pelvic dilatation that usually accompanies the anomaly. The present address as chairman of your section will report my personal experience with this procedure in seven such cases, recount the end results in them and indicate the conclusions that may be drawn from them and the nineteen similar cases reported in the literature.

Any outspoken pathologic change in the horseshoe kidney that is wholly responsible for the symptoms present provides the same clearcut and definite indications for correction of the lesion that the same lesion would provide in the normally formed kidney. As already indicated, such cases of horseshoe kidney associated with outspoken pathologic change do not enter the present considerations. However, with few exceptions reports in the literature indicate that in the consideration and management of horseshoe kidney the associated lesion has merely been assumed to be wholly responsible, has overshadowed the anomaly and has been the sole object of clinical attention and surgical attack, while the anomaly itself and its evils have been almost wholly neglected. This does not prove or admit that in such cases the anomaly is not just as important as the common renal lesion accompanying it or even that the anomaly may not have been responsible for development of the lesion present. To distinguish between cause and effect in any relationship that exists between the anomaly and the lesion associated with it is not my purpose here. The thesis deals only with horseshoe kidney per se as a clinical problem and does not touch on the problems presented by concomitant pathologic change.

Dr. Harry A. Wilmer rendered assistance in the search for references and prepared the accompanying bibliography and case summaries.
Read before the Section on Urology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

THREE GROUPS OF CASES OF HORSESHOE KIDNEY

For the present purpose all cases of horseshoe kidney may be divided into three groups and commented on as follows:

GROUP 1.—*Cases of horseshoe kidney without renal pathologic change or symptoms of renal origin.* In the majority of clinically recognized cases belonging to this group the urologic investigation leading to discovery of

the anomaly is prompted by painful abdominal symptoms of other than renal origin. In a large minority of cases the investigation is prompted by the patient's own discovery of an abdominal mass representing the isthmus of the horseshoe kidney or by the physician's similar discovery. In a small minority of cases belonging to this group the coincidence of urinary symptoms of vesical or urethral origin, not related to the upper

TABLE 1.—*Summary of Cases of Symphysiotomy for Horseshoe Kidney Reported in the Literature*

Case	Author and Year	Sex, Age	Clinical Data	Operation	Comment
1	Martinow, ³ 1910.....	♀ 40	Pulsating sensation in abdomen since childhood; pain above umbilicus of 4 years' duration; constipation; severity and frequency of pain increased; palpable mass	Chloroform anesthesia; transperitoneal approach; tumor found to represent horseshoe kidney; isthmus separated from aorta and divided; kidneys separated	Diagnosis by palpation: result, 5 months' complete relief
2	Rovsing, ³ 1911.....	♂ 23	Lower abdominal pain for 5 years occurring in attacks of sudden onset and lasting 3 hours; all attacks induced by activity; palpable mass moving with respiration	Transperitoneal approach; isthmus divided; separated left kidney retracted into normal position	Diagnosis by palpation under anesthesia; result, early complete relief
3	Malinowsky, ³ 1912.....	♀ 28	Persistent abdominal pain; hyperacidity; palpable mass	"Isthmus crushed"	Complete relief of pain; hyperacidity not relieved; result, early complete relief
4	Brongersma, ³ 1914.....	♀ 37	Since childhood bilateral lumbar pain more severe on left; later lower abdominal pain; left-sided colic; 2 attacks of bilateral pyelitis treated by lavage; previous operation for calculus; calculus not found; uterus and tubes removed	Transperitoneal approach; isthmus divided; kidneys retracted from midline	Result, 2 months "felt well"
5	Brongersma, ³ 1919.....	♂ ?	Pain in region of umbilicus; hematuria on 1 occasion following heavy lifting	Transperitoneal approach; isthmus divided; urinary fistula treated by nephrostomy	Diagnosis by operation: result early complete relief.
6	Kroiss, ³ 1922.....	♀ 29	Attacks of severe abdominal pain for 10 years; severe bilateral lumbar pain radiating to umbilicus occasioned by heavy lifting; pain relieved by flexion of spine, increased by lifting, coughing and sneezing	Transperitoneal approach; isthmus resected	Result, permanent complete relief
7	deGroot, ³ 1922.....	♂ 16	Attacks of abdominal pain of increasing severity 2 years; palpable mass	Transperitoneal approach; isthmus divided	Result, "recovery"
8	van Houtum, ³ 1922.....	♀ 37	Attacks of severe colicky lumbar and abdominal pain 1½ years; hematuria; pain and hematuria induced by exercise disappeared on rest; diagnosis by palpation under anesthesia, confirmed by pyelography	Transperitoneal approach; isthmus divided	Result, permanent relief
9	Kidd, ³ 1923.....	♀ 32	Lumbosacral pain in increasing severity for 4 years; pain increased by exercise; also occurred when lying down; partially relieved by lying on right side; previous operation with discovery of horseshoe kidney	Transperitoneal approach (3 months following previous operation); tense isthmus lying against aorta; isthmus divided; both kidneys retracted	Result, postoperative death on 5th day
10	Judd, Bransch and Scholl, ⁴ 1922	♀ ?	Not stated	Hydronephrosis; "... isthmus was divided and the diseased kidney rotated in order to permit the ureter to lie in normal position"	Result, 18 years of complete relief (personal communication)
11	Eggers, ³ 1922.....	♂ 18	Former period of vague right-sided pain of 10 years' duration followed by relief; 12 weeks prior to observation, sudden attacks of severe left-sided colic followed by passage of stone; recurrence of pain; palpable mass	"Left flank incision"; removal of stone; isthmus divided; left nephropexy	Diagnosis by operation: result, "recovery"
12	Papin, ³ 1922.....	♀ 32	Lumbar and abdominal pain of gradually increasing severity; palpable mass; diagnosis by pyelography	Extraperitoneal approach; division of isthmus	Result, early complete relief
13	Mintz, ³ 1925.....	♀ 33	Recurrent attacks of poorly localized pain; large palpable mass	Transperitoneal approach; division of isthmus	Diagnosis by operation: result, early complete relief
14	Lynch and Thompson, ⁵ 1934	♂ 36	"Backache" and pain referable to left kidney; relieved by lying down; pain referable to both kidneys of increasing severity for 15 days; tenderness in both flanks	Retroperitoneal approach; division of isthmus; division of anomalous vessels	Diagnosis by pyelography (?): complete relief of left-sided pain; right-sided pain improved; result, 3 months as noted
15	Chwalla, ⁵ 1935.....	♀ 29	Bilateral lumbar and umbilical region pain induced by heavy lifting of 4 years' duration; "abdominal colic" since childhood, recently more frequent; loss of appetite; pulsation in umbilical region; slept in semi-erect position for relief of pain	Transperitoneal approach; resection of isthmus	Result, 14 years of complete relief
16	Chwalla, ⁵ 1935.....	♀ 31	Abdominal and lumbar pain since childhood induced by extension of spine; attacks of great severity; palpable, very movable mass identified as horseshoe kidney	Transperitoneal approach; division of isthmus	Diagnosis by pyelography (?): result, 10 years of complete relief
17	Baker and Colston, ⁵ 1936	♂ 30	Intermittent right lumbar pain for 7 years, relieved by lying down	Extraperitoneal approach; division of isthmus; right nephropexy	Result, early complete relief
18	Baker and Colston, ⁵ 1936	♂ 52	Attacks of severe right lower quadrant pain for 1 year; right renal calculus	Extraperitoneal approach; division of isthmus; right pelvolithotomy; right nephropexy	Diagnosis by pyelography: result, early complete relief
19	Strode, ⁵ 1939.....	♂ 25	Abdominal pain for 6 years; tenderness in left kidney region; appendectomy 3 years previously without relief	1. November 1936, left retroperitoneal approach; resection of lower pole of right kidney; right nephropexy (?)	Diagnosis by pyelography: result, early complete relief

urinary tract, has indicated the urologic investigation leading to discovery of the anomaly.

In cases of this group the horseshoe kidney is of clinical importance only in a negative way. Since it is not affected by pathologic change and causes no symptoms, there is no more reason for surgical intervention with such a horseshoe kidney than there is reason to intervene surgically with an undiseased and symptomless kidney of normal form. The anomaly itself is of no surgical importance. In this group of cases the clinical burden is to discover the nonrenal cause of symptoms, if symptoms are present, and avoid the error, and possibly needless surgery, of assigning the anomalous though innocent horseshoe kidney as the cause of symptoms.

GROUP 2.—*Cases of horseshoe kidney with outspoken renal pathologic change and symptoms of renal origin.* Under competent medical care and modern methods of urologic diagnosis most cases of this group are clinically recognized, both the anomaly and associated lesion being clearly demonstrated. In most cases the associated lesion presents the same diagnostic and surgical problems that the same lesion would present in the normally formed kidney. These problems are made peculiar by presence of the anomaly, but the importance the anomaly may have beyond this has been largely neglected. A large majority of the reported cases of horseshoe kidney belong to this group. The associated lesions have been of great variety and include almost all of the common surgical renal lesions such as hydronephrosis, pyonephrosis, stone and tuberculosis.

In many cases of this group surgical correction of the "common renal lesion" associated with the anomaly is only one part of the problem present. Often it is found that correction of the lesion associated with the anomaly does not serve completely to right the evil. If the anomaly has been an etiologic factor in occurrence of the lesion its continuing presence may lead to recurrence of the lesion. If the symptoms have been due wholly or partly to the anomalous relationships they will not be completely relieved without surgical correction of the anomaly. Conceivably hydronephrosis occurring in association with horseshoe kidney may not be due to mechanical obstruction occasioned directly by the anomaly but instead to stricture, aberrant vessel or other form of obstruction not caused by the anomaly. Surgical correction of such an obstruction without correction of the anomaly should give complete relief provided the anomaly per se plays no part in the production of symptoms. The fact is, however, that most cases of hydronephrosis occurring in association with horseshoe kidney are due directly to mechanical obstruction made by the horseshoe kidney itself. This type of obstruction will be further considered in the comments concerning the cases of group 3.

In many cases of this group an unsatisfactory result of operation is recognized but there has been habitual failure to recognize that continuing presence of the anomalous relations and failure to correct them surgically are responsible for the unsatisfactory outcome.

In this combination of an outspoken renal lesion associated with horseshoe kidney it may be difficult or impossible to say what part of the symptom complex is caused by the lesion and what part is caused by the anomaly. Unless there are good indications to the contrary, it may be best in such cases to proceed on the

assumption that the associated lesion is solely responsible, surgically correct it and leave the anomalous relationships undisturbed. Should an unsatisfactory result ensue, the responsibility of the anomaly for it should be investigated, and if good indications are found the anomalous relationships should be corrected by division of the isthmus and normal positioning of the separated kidneys.

GROUP 3.—*Cases of horseshoe kidney with symptoms of renal origin but without renal pathologic change other than some degree of pelvic dilatation.* The cases of this group are the ones most intimately concerned in the present thesis.

There is good reason to believe that a large number of cases of horseshoe kidney belong to this group—and yet with few exceptions nothing has been done about them. They have been nearly like the weather: every one talks about the weather but no one does anything about it.

Many cases of horseshoe kidney with pyelograms showing no significant departure from normal except for the anomaly are recognized clinically and many of them have been reported. They may belong to group 1, in which the anomaly is not the cause of pain or any other clinical manifestations whatever. As already indicated, such cases are of no clinical importance. However, in many cases belonging to this group the malformation itself is directly the cause of pain and other symptoms, which prompt investigation, leading to discovery of the anomaly.

If symptoms are present, the burden of proof goes with saying they are not caused by the horseshoe kidney. This is particularly true when the symptoms are suggestive or typical of renal origin. However, it appears that the horseshoe kidney without any significant pathologic change may cause vague and indefinite symptoms not suggestive, and by no means typical, of renal origin. Gutierrez emphasizes this point. Among these symptoms are vague abdominal pain or "belly ache," constipation and other digestive disturbances.

From personal experience I am not familiar with such cases, for in all the cases here reported in support of the present thesis symptoms typical of renal origin were present.

Nor can I say from personal experience that absence of significant pathologic change properly defines this group of cases. In some of the cases here reported there was obvious pathologic change in the form of pelvic dilatation while in others the pyelogram after operation has shown disappearance of what was originally considered insignificant dilatation of the pelvis in the preoperative pyelogram. In the light of this change in response to operation it becomes obvious that the slight dilatation present before operation in these cases actually should have been regarded as significant.

My own observations in the personal cases here reported make it appear certain that the various degrees of pelvic dilatation usually present in cases of this group are due directly to mechanical obstruction of the ureters occasioned by the anomaly: abnormal insertion of the ureter into the pelvis and contact of the ureter with the isthmus. These malrelationships were clearly evident in every case. The pelvic dilatation present varied from insignificant dilatation to outspoken hydronephrosis (case 5). Even in the latter case no other possible cause of obstruction could be found. The

dilatation, whatever its degree, regularly diminished in response to surgical restoration of normal relationships of the ureter.

However, in the literature and particularly in the monograph of Gutierrez are found reports of cases with

Fig. 1 (case 1).—A, preoperative right and left pyelo-ureterograms; B, postoperative right and left pyelo-ureterograms.

pyelograms showing no deformity whatever suggestive of pathologic change apart from the anomaly but presenting either symptoms typical of renal origin or vague symptoms possibly of renal origin. To determine surgical indications, if any, in the latter cases is a difficult problem. If comprehensive investigation fails to disclose an extrarenal lesion capable of causing the vague symptoms then there is much reason to believe that the symptoms will be relieved by correction of the anomalous relations, by division of the isthmus and nephropexy on one or both sides.

PROPER CLINICAL MANAGEMENT OF HORSESHOE KIDNEY

In the foregoing discussion a problem concerning the clinical management of horseshoe kidney has been posed. The comments made anent the matter already

Fig. 2 (case 2).—A, preoperative right and left pyelo-ureterograms; B, postoperative bilateral pyelogram.

have indicated the chief conclusion to be drawn. That conclusion is:

The anomaly horseshoe kidney not affected by concomitant pathologic change of significance may be productive of painful and other symptoms and insidious development of renal disease and can be restored to normal anatomic relations with relief

of symptoms and arrest of the insidiously developing renal disease by appropriate surgical intervention—symphysiotomy and nephropexy.

This conclusion is based on cases reported in the literature and the personal cases to be reported here.

Prior to 1930 when the first personal case was encountered there had been reported in the literature only twelve cases of horseshoe kidney in which symphysiotomy with or without nephropexy had been made.³ All of these were in Europe and in all save one, the case of Papin, operation by the transperitoneal approach was done. Unfortunately the eventual end results in these cases are not described, but the immediate symptomatic result was reported as excellent in all of the eleven surviving patients.

In a paper dealing with renal anomalies in general published in 1922, Judd, Braasch and Scholl⁴ mention but do not otherwise report a case of horseshoe kidney in which the isthmus was divided and "the right portion of the divided kidney was rotated in such a way as to make the ureter lie in its normal position." By personal communication it is learned from Dr. Braasch

Fig. 3 (case 3).—A, preoperative right and left pyelo-ureterograms; B, postoperative excretion urogram.

that eighteen years after operation this patient was alive and well, the result of operation appearing to be excellent.

The twelve European cases and the case of Judd, Braasch and Scholl, all reported prior to 1930, appear as cases 1 to 13 inclusive in the cases of symphysiotomy for horseshoe kidney reported in the literature summarized in table 1.

Since 1930, when the series of personal cases was started, there have been reported in the literature six more cases of this sort.⁵ The results in three cases are

3. The twelve cases were reported by:

stated to be excellent eight years, ten years and fourteen years after operation. In the remaining three cases only the immediate result is stated but this was excellent in all. These six cases reported since 1930 appear as cases 14 to 19 inclusive in table 1.

My six cases of horseshoe kidney and one case of unilateral fused kidney corrected by symphysiotomy and nephropexy on one or both sides, together with the nineteen cases reported in the literature, make a total of twenty-six cases for use in appraising division of the isthmus and nephropexy in cases of fusion anomaly.

My six personal cases are reported in summary and illustrated as follows:

REPORT OF CASES

CASE 1.—This case, from the urologic service of the Ancker Hospital, was originally reported in 1932 by my associate in the service, Philip F. Donohue.⁶

A woman aged 32 had had pain in the right lower quadrant of the abdomen for twelve years. A mass to represent the isthmus was not palpable. Pyelograms (fig. 1A) had the typical features of horseshoe kidney: low position, long axis oblique toward the midline below and medial direction of the inferior calices. There was slight dilatation of the pelves.

Fig. 4 (case 4).—A, preoperative urinary tract roentgenogram (left half; opaque catheter in ureter); B, preoperative right and left pyelo-ureterograms; C, postoperative left pyelo-ureterogram.

In March 1930, through a right flank incision, extraperitoneal exposure of the right half of the horseshoe kidney was made. The isthmus was divided and a right nephropexy was done. The operation gave complete and permanent relief of the right-sided pain.

Eight months after the operation the patient began to have pain on the left side exactly like the pain on the right side before operation. Left nephropexy was done, followed by complete and permanent relief of the left-sided pain. The pyelograms (fig. 1B) made long after the two operations showed completely normal pelves and disappearance of the pelvic dilatation.

Comparison of the before and after pyelograms (fig. 1) show beautifully the anatomic accomplishment of operation. This is accompanied by complete symptomatic relief. The dilatation originally present appeared to be insignificant but its disappearance the result of operation suggests that actually it was significant.

On June 1, 1940, more than ten years after operation, the patient reported continuing complete relief. There seemed to be no warrant to make another check-up pyelogram at that time.

CASE 2.—A woman aged 21 had had periodic bilateral back-ache and attacks of severe pain in the right flank and right lower quadrant of the abdomen for seven years. The right and left pyelograms (fig. 2a) showed the typical features of horseshoe kidney and slight pelvic dilatation.

Oct. 15, 1931, division of the isthmus and right nephropexy were made with immediate and permanent relief of the right-sided pain. During convalescence the patient began to have pain on the left side exactly like that on the right side before operation. Left nephropexy, December 8, was followed by complete and permanent relief of the left-sided pain.

Fig. 5 (case 5).—A, preoperative bilateral pyelo-ureterogram; B, postoperative right and left pyelo-ureterograms.

Two years after operation a bilateral pyelogram (fig. 2B) showed restoration to normal. Comparison of the before and after pyelograms (fig. 2) shows clearly what the operation accomplished.

On June 1, 1940, nine years after operation, the patient reported continuing complete relief. There seemed to be no warrant to make another check-up pyelogram at that time.

CASE 3.—A woman aged 25 had periodic pain in the right flank and right side of the abdomen for several years. Pyelograms (fig. 3A) showed the typical features of horseshoe kidney with slight dilatation of each pelvis. Resection of the isthmus and right nephropexy were done in July 1933, followed by complete and permanent relief of the right sided pain.

Within a year the patient began to have pain on the left side exactly like that present on the right side before operation. Left nephropexy in January 1935 was followed by complete and permanent relief of the left-sided pain.

Fig. 6 (case 6).—A, preoperative bilateral pyelo-ureterogram; B, postoperative bilateral pyelo-ureterogram.

Excretion urograms (fig. 3B) made in April 1938, five years after the first operation, showed restoration to near normal. Comparison of the before and after pyelograms (fig. 3) shows well the anatomic accomplishment of the operation.

CASE 4.—This was the only case of failure. A man aged 38 had severe pain in the left flank, mild pain in the right flank and abdominal pain for several years. There was a stone in

the left kidney (fig. 4A) and with it bilateral hydronephrosis (fig. 4B) and deformity typical of horseshoe kidney. In June 1934 left pelviolithotomy, division of the isthmus and left nephropexy were done.

Later it was discovered the stone had been incompletely removed. Although the position of the kidney had been restored to near normal and the pelvic dilatation was slightly decreased (fig. 4C) the infection persisted and secondary nephrectomy was done eight months later.

CASE 5.—A woman aged 30 had had frequent severe pain in the right flank and right side of the abdomen for five years and occasional mild pain in the left flank and left side of the abdomen. The bilateral pyelogram (fig. 5A) showed the typical features of horseshoe kidney and bilateral hydronephrosis. In September 1934 division of the isthmus and right nephropexy were performed followed by gradual but finally complete relief of pain on the right side.

A year or so later the originally mild pain in the left flank and abdomen greatly increased. Left nephropexy in July 1938 was followed by complete and permanent relief. Relief of subjective symptoms has been complete and permanent. The most recent check-up pyelogram (fig. 5B) was made June 5, 1940, five and one-half years after the first operation and two years

right lower quadrant of the abdomen. The pyelogram (fig. 7A) showed the typical features of unilateral fused kidney with crossed ectopia of the left and lower segment.

For relief of the left-sided pain, two operations were contemplated. The pain appeared to have its origin in the left half of the fused kidney. Preliminary to any surgical attack on the "crossed-ectopic" left half of the fused kidney it seemed wise first to divide the isthmus and fix in normal position the separated right kidney. With the right half of the fused kidney thus restored to normal position and normal function, it would then be possible safely to perform a left nephrectomy if later operation on the left side disclosed vascular attachments or other technical difficulties making impossible a conservative procedure.

In June 1937, through a right flank incision with extra-peritoneal approach to the kidney, division of the isthmus and right nephropexy were done. Through this incision it was possible to displace the separated left kidney across the midline, though restoration of the left kidney to a completely normal position of course was not possible with this exposure.

The result to date, three years after operation, is excellent, there being complete relief of the left-sided pain complained of before operation. Since operation the patient has gone through an uneventful pregnancy terminated by normal delivery. In view of all this, no indication is found for doing the contemplated second operation on the left side.

The most recent check-up pyelogram (fig. 7B) was made June 5, 1940, three years after operation. It gives very poor outlining of the lower or left pelvis but sufficient to show that its position is somewhat improved. The right pelvis is well up in normal position. A comparison of this with the pyelogram made before operation shows what was accomplished (fig. 7).

COMMENT

In all of these cases a lumbar incision and extra-peritoneal approach to the kidney were employed. In all cases excellent exposure was secured: the procedure was carried out with facility and no formidable difficulty was encountered. In all cases relatively smooth convalescence followed the surgical procedure, and there was no mortality.

Items of interest in the occurrence and management of these cases are the following:

Six of the seven patients were women, all of whom were in the second or third decade. One patient was a man aged 38.

In all cases the chief complaint was pain and in most instances its character was fairly typical of renal origin. In all the cases obstruction and varying degrees of pelvic dilatation were demonstrated and in some there were varying degrees of upper tract infection and pyuria. In two of the cases the degree of pelvic dilatation amounted to outspoken hydronephrosis and one of these was complicated by stone.

In all cases operation was undertaken with relief of pain its chief objective. In all save one case (case 4) this object has been fully attained, with complete relief of painful symptoms. The one case of failure was due to faulty management, failure to remove a stone completely.

It should be noted that, in three cases (1, 2 and 3) of unilateral pain, division of the isthmus and relief of pain on the side of operation was followed in different periods by development of identical pain on the opposite side and that in these three cases correction of the abnormal position of the opposite half of the horseshoe kidney gave complete relief of the newly developed pain on the opposite side. In another case (case 5) originally mild pain on the opposite side gradually increased and a year and a half after the first operation was com-

Fig. 7 (case 7).—A, preoperative bilateral pyelo-ureterogram; B, postoperative bilateral pyelo-ureterogram.

after the second operation. A comparison of this with the original pyelogram (fig. 5) shows what was accomplished by the operation.

CASE 6.—A girl aged 19 years at first had attacks of severe pain in the right lower quadrant of the abdomen. Later there was constant bilateral lumbar pain. The pyelogram (fig. 6A) showed the typical deformity of horseshoe kidney and grade 1 dilatation of each pelvis. On the left side there was duplication of the pelvis and upper ureter.

In July 1937 division of the isthmus and right nephropexy were performed. Following operation there were two attacks of acute pyelonephritis. Apart from these there has been complete and permanent relief of the right lower quadrant pain and of bilateral lumbar pain. The most recent check-up pyelogram (fig. 6B) was made June 6, 1940, three years after operation. It showed normal position of the right pelvis but no decrease of dilatation and no change in position of the left pelvis.

A comparison of this recent pyelogram with the original preoperative pyelogram (fig. 6) shows what was accomplished by operation.

CASE 7.—This was a case of unilateral fused kidney and was originally reported in the February 1930 issue of *International Abstracts of Surgery*.⁷

A girl aged 18 complained of left-sided abdominal pain for three years, at times very severe. A mass was palpable in the

7. Foley, F. E. B., and Wilmer, H. A.: *Internat. Abstr. Surg.* 70: 155-170, 1940, in *Surg., Gynec. & Obst.*, February 1940.

pletely relieved by nephropexy on the second side. In one case of bilateral pain (case 6) division of the isthmus and nephropexy on only one side gave relief of pain on both sides. In one case of unilateral fused kidney (case 7) left-sided pain was relieved by symphysiotomy and right nephropexy.

These seven cases make by far the largest individual experience thus far reported—in fact they represent almost a third of the total experience. In all save one case the eventual end result has been excellent ten years after operation in the earliest case, three years after operation in the most recent case.

The reports in the literature state the eventual end result in only three cases: excellent fourteen years, ten years and eight years after operation. In the case of Judd, Braasch and Scholl the result was excellent eighteen years after operation. In the remaining fifteen cases reported in the literature only the immediate result up to a few months after operation is stated, but in all it was excellent.

My own experience indicates that an immediately favorable result will prove to be a permanently favorable result if the case is followed long enough to bring the proof. At least among my seven cases there was only

TABLE 2.—*Results of Symphysiotomy With or Without Nephropexy*

Excellent or good results—permanent.....	10 38%
Excellent or good results—total.....	24 92%
	26

one eventual poor result (case 4) and this was due to mismanagement—the failure to remove a calculus completely. This personal experience, indicating that an immediately favorable result will be permanent, increases the significance of the early favorable results reported in the literature.

SUMMARY AND CONCLUSIONS

The eighteen cases reported in the literature, the case of Judd, Braasch and Scholl followed by personal communication and my seven cases here reported are summarized in table 2 and the results may be stated as follows:

There was a total of twenty-six cases.

There was one postoperative death.

There was one poor result, which was due to mismanagement.

There were twenty-four good results. Of these, fourteen were reported as early results and ten were reported as permanent results.

The material presented warrants the conclusions that:

1. The anomaly horseshoe kidney not accompanied by any significant pathologic change may be productive of painful and other symptoms.

2. The symptoms caused by the anomaly horseshoe kidney can be relieved and normal anatomic relations can be restored by division of the renal isthmus and nephropexy on one or both sides.

ACUTE ASCENDING PARALYSIS

CLINICAL AND PATHOLOGIC REPORT ON CASES WITH FATAL TERMINATION

RUSSELL N. DEJONG, M.D.

ANN ARBOR, MICH.

In 1859 Octave Landry¹ described a case of acute ascending paralysis in which there were no changes in sensation, muscular atrophy or disturbances of the sphincters, and no abnormalities were observed in the postmortem examination. Cases of ascending paralysis in which the clinical course resembled the one described by Landry have been called Landry's paralysis by many observers, and a definite clinical syndrome has been described. A previously healthy individual, after suffering from mild prodromal symptoms such as malaise, paresthesias in the lower extremities, anorexia, constipation and occasionally slight fever, develops a sudden flaccid paralysis of the lower extremities which rapidly ascends, involving next the abdominal muscles, the intercostals, the upper extremities and in fatal cases the muscles supplied by the bulbar nerves. Cases of descending paralysis have also been described, but these occur less frequently. The process may result in death within a few days or weeks, or if improvement does take place there may be complete recovery, the function returning first in the muscles last affected.

An infectious or toxic etiology has usually been ascribed to the condition, and enlargement of the spleen, hyperplasia of the lymph nodes, albuminuria and nephritis have been observed in some cases.² Among the infectious diseases that have been complicated by an ascending paralysis are syphilis, tuberculosis, diphtheria, influenza, typhoid, measles, mumps, malaria, pertussis, encephalitis, rabies, Rocky Mountain fever, smallpox, vaccinia, pneumonia, anthrax, varicella, gonorrhea and herpes. Rabies vaccine, diphtheria and tetanus antitoxin, alcohol, lead, arsenic and hematophyria have been reported as toxic etiologies. In a few instances organisms have been isolated from the cerebrospinal fluid or the spinal cord,³ but bacteriologic studies have given no consistent or conclusive results. A recent translator of Landry's original description and other authors believe that vitamin deficiency should be considered as an important etiologic factor,⁴ but this hypothesis remains to be proved. The term Landry's paralysis has also been erroneously applied to cases of poliomyelitis, transverse myelitis, myelomalacia⁵ and other varieties of myelitis of known etiology characterized by an ascending type of paralysis, but these conditions should obviously be differentiated from the true Landry type.

From the Department of Neurology, University of Michigan Medical School and University Hospital.

Read before the Section on Nervous and Mental Diseases at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

5. Low, A. A.: Acute Ascending Myelomalacia, *Arch. Neurol. & Psychiat.* 21: 594 (March) 1929.

The pathologic observations in cases classified as Landry's paralysis have been varied and inconsistent. The earlier writers believed that pathologic changes were absent; this opinion may have arisen as the result of the lack of technical facilities at the time, although cases are still being reported in which no lesions are found. Oppenheim⁶ stated that the postmortem appearances were indefinite and contradictory; in many cases the examination was negative, in some there were disseminated foci of inflammation and exudation with capillary hemorrhages and swelling of the axis cylinders, and others showed inflammation of the anterior horns or a combination of a neuritis and a myelitis. He felt that in most cases the conditions resembled those seen in polyneuritis without being identical with it. Cadwalader⁷ described hyperemia and edema of the gray matter of the spinal cord with varying changes in the anterior horn cells but stated that there appears to be no certain method of determining whether the disease process originates in the nerve fibers, in the spinal cord, or in both. At the present, however, most authors agree that purely degenerative changes take place either in the anterior horn cells or in the peripheral nerves, but there are no evidences of inflammation or infiltration, no glial proliferation, and no degenerative changes in the white matter of the spinal cord.⁸

Many authors have questioned the use of the term Landry's paralysis and the consideration of the condition as a nosologic entity.⁹ As early as 1891 Eichberg stated that the name was unscientific and should be dropped. Much misunderstanding has resulted, however, from the fact that many dissimilar conditions have been classified as Landry's paralysis. Eichberg's own case obviously did not belong to the Landry group, as it showed an acute inflammatory reaction in the anterior horn cells, the perivascular spaces and the meninges. Other authors have added to the confusion by using the term Landry's paralysis for cases of poliomyelitis and polyneuritis in which the paralysis was of an ascending nature. Grinker,¹⁰ for example, states that poliomyelitis is the most common cause of Landry's paralysis and that diphtheritic polyneuritis is the next in frequency. Cobb and Coggeshall¹¹ say that most cases diagnosed as Landry's paralysis are fulminating examples of ordinary infantile paralysis. According to Osler¹² the differentiation between multiple neuritis and Landry's paralysis is often difficult, and it may be impossible in cases with sensory changes. Taylor and McDonald¹³ considered ascending paralysis as a transitional form

between conditions in which the pathologic changes are predominantly in the spinal cord and a complicated group of polyneuritides. Collier¹⁴ believes that the separation of Landry's paralysis and polyneuritis is artificial and that Landry's paralysis is a polyneuritis with associated spinal cord involvement; he¹⁵ even went so far as to say, in his Morrison Lectures before the Royal College of Physicians of Edinburgh in 1932, that Landry's paralysis is one of the most characteristic of all forms of peripheral neuritis—a destruction of function, rapidly advancing, spreading by tissue continuity, without discoverable histologic changes and, when not fatal, rapidly and completely recovering, and that every grade of transitional form between the rapidly spreading Landry's paralysis and the slowly advancing types of peripheral neuritis may be encountered.

Attempts at classification and differentiation of the various types of ascending paralysis have been of some value in understanding the group as a whole but have not entirely clarified the subject. Some authors¹⁶ have differentiated the poliomyelitic and polyneuritic varieties from those showing little or no pathologic change. Pette and Környey¹⁷ separated cases with purely degenerative changes, apparently on a toxic basis, from those showing outspoken signs of inflammation. They subdivided instances of Landry's paralysis showing inflammatory changes into those in which the evidences of inflammation were predominantly central, or cases of atypical poliomyelitis, and those in which the pathologic changes were predominantly peripheral. Two instances of the latter group were described by them and classified as cases of Landry's paralysis, but both showed sensory changes and loss of sphincter control, thus making the clinical diagnosis doubtful, and in addition the postmortem examination revealed lymphocytic and plasma cell infiltrations in the ganglions, the nerve roots and the meninges. Juba¹⁸ described a similar case in which there were degenerative changes associated with infiltrations in the spinal ganglions, but he spoke of this as a polyneuroganglioradiculitis, which is obviously a better term.

Certain authors believe, however, with Gordinier¹⁹ that ascending paralysis is a specific type of myelitis of unknown etiology which can be differentiated, both clinically and pathologically, from poliomyelitis and polyneuritis, even in complicated cases. The former can, as a rule, be excluded by its epidemiologic features, clinical signs, characteristic cerebrospinal fluid changes and definite patho-anatomic picture. In polyneuritis there is simultaneous involvement of both sensory and motor nerves, the process being manifest in various portions of the body but failing to follow the distribution usually seen in acute ascending paralysis. in conditions such as "infectious neuronitis" (Foster Kennedy; Gilpin, Moersch and Kernohan,²⁰ and others) and in the cases of ascending paralysis in troops described by Casamajor,²¹ a clinical and pathologic differentiation can usually be reached. The same is true of the cases of polyneuritis with albuminocytologic dissociation described by Guillain and Barré.²²

In an effort to evaluate these varying points of view and to come to some conclusions as to the justification of the use of the terms ascending paralysis or Landry's paralysis, some cases that have recently been studied both clinically and pathologically in the University Hospital have been reviewed.

REPORT OF CASES

CASE 1.—M. K., a painter aged 65, had noticed shooting pains in the feet for several months. Three weeks before admission he had diarrhea and a slight head cold and two weeks later had suddenly become nauseated, vomited, and noted cramping pains in the lower part of the abdomen. Following this he had weakness and later an ascending paralysis, first involving the feet, then the thighs, trunk and upper extremities. There was tingling of the hands and feet but no definite loss of sensation, and there was no disturbance of bowel or bladder control. Two days before admission he developed hoarseness, dysphagia, and weakness of the neck muscles, and shortly after this difficulty in breathing.

On admission the patient was dyspneic and cyanotic. Respirations were intercostal in type. Speech was reduced to a whisper and swallowing was difficult. There was limitation of lateral rotation of the eyeballs to each side; the ocular fundi were normal, as was the reaction of the pupils. There was weakness of the muscles of facial expression on both sides, and

trapezius muscles. The patient was unable to move his extremities. The tendon and abdominal reflexes were absent. There was no response following plantar stimulation. The sensory examination was unsatisfactory but no definite disturbance in sensation was elicited.

Fig. 2 (case 1).—Section of anterior horn cells showing shrinkage and pyknosis. Nissl stain; Zeiss objective 40 \times ; ocular F 2.

Because of the marked difficulty in breathing the patient was placed in a respirator on admission to the hospital, and as a result further examinations including those of the cerebrospinal fluid could not be carried out. There was a gradual failure of respiration and circulation, and death occurred in forty-eight hours.

The postmortem examination revealed an acute purulent bronchitis and bronchopneumonia with atelectasis, emphysema and pulmonary congestion. The brain and spinal cord were edematous and hyperemic and the meninges were congested. There were many small hemorrhages into the meninges and the gray matter of the cord. The predominant microscopic pathologic changes were noted in the nerve roots and the spinal ganglions. There were large deposits of lipoids in the periphery of the neurons and within the nerve fibers, as demonstrated both by scarlet red and by osmic acid stains (fig. 1). The structure of the ganglions and nerve fibers was otherwise unchanged, the myelin was not appreciably broken down, and there was no evidence of inflammation. Nissl stains of the spinal cord showed shrinkage, pyknosis and varying degrees of chromatolysis of the anterior horn cells (fig. 2), and scarlet red and osmic acid stains showed lipoids within the neurons. There were many small hemorrhagic areas in the gray matter, some of which were surrounded by minute areas of necrosis. There were no evidences of infiltration, inflammation or exudation in the nerves or the spinal cord, and there was no destruction of the myelin sheaths. No definite pathologic changes were demonstrable in the nuclear area of the pons or medulla.

CASE 2.—Mrs. B. S., a white woman aged 48 whose past medical history was without significance, had been well until two weeks before admission to the hospital, at which time she had an attack of respiratory difficulty diagnosed as asthma and relieved by oral and hypodermic medication. One week later she noticed heaviness and progressive weakness of the feet, which ascended to involve the legs and later the arms and hands. There were paresthesias in the hands and feet, but there was no definite loss of sensation.

At the time of admission the patient was dyspneic and moderately cyanotic. Moist rales were heard throughout the lungs and there was an area of dullness at the base of the left lung. There was no disturbance of superficial sensation or of sense of position; vibratory sense was slightly diminished at the ankles, but deep pain sense was increased in the calf muscles and achilles tendons. The pupils reacted normally to light and in accommodation. The extra-ocular movements were

Fig. 1 (case 1).—Section of deposits of lipoids in the periphery of the neurons of the spinal ganglions and within the nerve fibers. Scarlet red stain; Zeiss objective 40 \times ; ocular F 2.

the soft palate could not be elevated. The tongue could not be protruded beyond the lips, but there was no atrophy or tremor. There was bilateral weakness of the sternocleidomastoid and

normal. There was a slight but definite weakness of the muscles supplied by the left facial nerve. Articulation was normal. The sternocleidomastoid and trapezius muscles contracted normally and the tongue protruded in the midline. Aside from shrugging of the shoulders the patient was unable to carry out any movement of the upper or lower extremities. There was no atrophy, and no fibrillations were seen. All tendon and cutaneous reflexes were absent. There were no pyramidal tract signs. The urinalysis, blood count, and blood Kahn test gave negative results. The spinal fluid pressure was 150 mm. of water, with no block, and the fluid contained one lymphocyte per cubic millimeter; the Pandy and Nonne-Apelt tests were strongly positive, the total protein content was 111 mg. per hundred cubic centimeters, the Kahn reaction was negative, the colloidal gold curve was 0011100000, and the mastic curve was 122100. Examination of the urine, hair and nails for lead and arsenic was carried out with negative results.

The paralysis of the extremities continued unabated, and two days after admission the patient noted difficulty in swallowing and talking with progressive respiratory distress. Pneumonia developed and death occurred two weeks after admission.

The postmortem examination showed bronchopneumonia in the lower lobe of the left lung and atelectasis in the lower lobe of the right. Gross examination of the brain revealed pronounced hyperemia. In the spinal cord the predominant congestion was in the anterior horns, the cells of which showed marked swelling with displacement of the nuclei. The tigroid substance was broken down; in some cells it was evenly distributed throughout and dustlike in appearance, while other cells stained a deep pinkish blue with thionin and showed no details. Many of the swollen cells contained large vacuoles, and some with three or more exhibited a honeycombed appearance (fig. 3). Scarlet red and Marchi stains showed accumulations of lipoids within the neurons. The vessels of the cord were congested and engorged but there was no evidence of infiltration or exudation and no degeneration of the myelin sheaths. The motor nuclei within the medulla showed changes similar to those present in the anterior horn cells. There was no inflammatory reaction in the ganglions and no definite evidence of any pathologic process in the peripheral nerves.

Fig. 3 (case 2).—Section of anterior horn region showing swelling and vacuolization of neurons. Nissl stain; Zeiss objective 40 \times ; ocular F 2.

CASE 3.—M. P., a girl aged 18 months, developed what appeared to be pain in the legs and later in the arms, followed by a complete paralysis of the lower and a partial paralysis of the upper extremities. There was a brief elevation of temperature at the time of the onset of the symptoms. Six weeks later respiratory difficulty appeared and the temperature again became elevated.

At the time of admission to the hospital the patient was dyspneic and cyanotic. The respirations were 30 per minute,

the pulse rate was 130 and the rectal temperature was 101 F. There was dulness with bronchial breathing over the base of both lungs. The pupils reacted normally and there was no apparent difficulty in talking or swallowing. There was a flaccid paralysis of the upper and lower extremities. The triceps reflexes were diminished, and the biceps, patellar and achilles reflexes were absent. The abdominal reflexes were

Fig. 4 (case 3).—Section of anterior horn region showing outspoken primary irritation of the neurons with chromatolysis and swelling. Nissl stain; Zeiss objective 40 \times ; ocular F 2.

not obtained. There was no Babinski sign. Superficial and deep pain sensations were apparently normal. There was no demonstrable muscle tenderness and there were no signs of meningeal irritation. The urinalysis and the Kahn tests on the blood gave negative results. Blood count showed 13,050 leukocytes per cubic millimeter, 79 per cent of which were polymorphonuclear cells. A spinal puncture was not performed.

The child was placed in an oxygen tent but her respiratory difficulty increased and she became unable to swallow. Death occurred twenty-four hours after admission.

The postmortem examination showed a severe bilateral, confluent, purulent, lobular pneumonia. There were moderate congestion and edema of the brain, meninges and spinal cord but no other gross pathologic abnormalities. Microscopic examination showed pronounced changes in the anterior-horn cells, especially in the lumbar and sacral segments. The cells were greatly swollen and many were vacuolated. The tigroid substance was disintegrated and broken down into fine dustlike particles which stained a pinkish blue with thionin. The nuclei were either shrunk and pushed to the periphery of the cells or were completely destroyed (fig. 4). In other segments, especially those of the thoracic cord, there were fewer swollen cells but many which stained a deep blue so that few details could be made out, and some which were reduced to indistinctly outlined bodies filled with disintegrated tigroid material. In certain sections the neurons in the anterior horns were greatly reduced in number and those which remained were small and shrunk. There were no signs of inflammation or glial proliferation and there was no degeneration of myelin. The peripheral nerves were normal. There were no demonstrable changes in the medulla.

CONCLUSIONS

These are instances of acute ascending paralysis of unknown etiology. The pathologic changes were not identical, but in all there were evidences of a degenerative process involving the motor nuclei or the peripheral nerves or both. There were no signs of inflammation, such as cellular infiltration or glial proliferation, and no degenerative changes in the white matter of the spinal cord. The predominant gross pathologic finding was hyperemia of the anterior horn region. The outstanding microscopic change, the degen-

eration of the neurons, assumed different forms. In case 1 it consisted of shrinkage and pyknosis, which may be considered as a primary phenomenon, but it was accompanied by degenerative changes in the nerve roots and the spinal ganglions. In case 2 there were swelling, chromatolysis, displacement and fragmentation of the nuclei, and vacuolization, which is assumed to indicate an axonal type of degeneration secondary to changes in the axis cylinders. Case 3 showed a pronounced axonal reaction in some segments with pyknosis and reduction in the number of the neurons in others. It can be assumed from these observations that the degenerative process is one that involves either the motor nuclei or the peripheral nerves or both and is therefore characterized by involvement of part or all of the final common pathway of the motor impulses. In spite of some variability in the changes they were purely degenerative in all cases, and to a certain extent each showed some evidence of both pyknosis and swelling. It is entirely possible that the syndrome is a transitional form between certain types of polyradiculoneuritis (Guillain-Barré syndrome) and varieties of myelitis and encephalitis.

The etiology of the process cannot be arrived at from this study. As there are no signs of inflammation and the changes in the nervous system are essentially degenerative in nature, it can probably be assumed that we are dealing with an acute toxic process affecting both the central and the peripheral nervous system.²³ A filtrable virus etiology has been suggested, but this has not yet been proved.²⁴

Precedent has established the use of the terms Landry's paralysis and acute ascending paralysis. Diller²⁵ in 1902 stated: "The term Landry's paralysis cannot be dropped. It has been used too long to be erased from our nomenclature." If these terms are to be used, however, they should not be interpreted as signifying a definite nosologic entity due to a single etiology. The terms should be used only in those cases in which the clinical syndrome is similar to that described by Landry and no definite etiology such as poliomyelitis or some specific toxin or infection is suspected. When the foregoing terms are used they should be considered as descriptive of the mode of onset and progression of the condition² rather than as a final diagnosis. Cases in which the etiology is known but the syndrome closely resembles that seen in acute ascending paralysis may be spoken of as cases of Landry's syndrome.

Normal Food Requirements.—Gillett has suggested that the family food budget be divided into fifths: one fifth for vegetables and fruits, one fifth or more for milk and cheese, one fifth or less for meat, fish and eggs, one fifth or more for bread and cereals and one fifth or less for sugars, fats and other groceries and food adjuncts. Whatever the level of food expenditure, at least as much should be spent for milk (including cream and cheese) as for meats, poultry and fish, and as much should be spent for fruits and vegetables as for meat, poultry and fish.—Smilie, Wilson G.: *Public Health Administration in the United States*, New York, Macmillan Company, 1940.

POLYRADICULONEURITIS (GUILLAIN-BARRÉ SYNDROME)

FOLLOWING THE USE OF SULFANILAMIDE AND
FEVER THERAPY

PAUL H. GARVEY, M.D.

NATHANIEL JONES, M.D.

AND

STAFFORD L. WARREN, M.D.

ROCHESTER, N. Y.

During recent years two valuable therapeutic agents, sulfanilamide and fever therapy, have been added to the armamentarium in the treatment of disease. However, like other therapeutic measures, they may be accompanied or followed by undesirable effects in a certain percentage of cases. It is often difficult to decide, when two therapeutic agents are used concomitantly or consecutively, which agent is responsible for the favorable effect on the disease or, in some instances, even the undesirable complication.

Numerous toxic manifestations have been described following the use of sulfanilamide and its derivatives. Reports indicating a toxic action of sulfanilamide on the peripheral nervous system are few. Ornsteen and Furst¹ reported a case of peripheral neuritis which followed the ingestion of 130 Gm. of sulfanilamide. Janet² observed one case of multiple neuritis of the arm and thorax which lasted only three days. Vaughn³ recently reported a case of neuritis of the left anterior tibial nerve occurring in a patient with gonorrhea during treatment with sulfanilamide. This was the only case which he observed in 650 cases in which intensive sulfanilamide therapy was administered. A case of optic neuritis was reported by Bucy.⁴ However, peripheral neuritis has been frequently reported following the use of disulfyl-sulfanilamide. Recently we have observed two cases of peripheral neuritis which developed in patients treated for staphylococcal infections with sulfamethylthiazole.

Certain evanescent symptoms referable to the nervous system may occur during fever treatment. In this clinic we have occasionally observed such symptoms as delirium, coma, convulsions, vomiting and localized muscular weakness. These symptoms have been attributed to dehydration, cerebral edema, anoxemia and in a few cases of syphilis probably actual vascular lesions in the central nervous system. These symptoms are found during or immediately following treatment.

During the past two years we have observed six cases in which a more extensive and rather definite, stereotyped syndrome developed from ten to sixteen days following fever treatments of fifteen hours at 41.5 C. (106.7 F.). Nothing similar had been noted following the treatment of approximately 1,100 fever cases since 1930, and the syndrome is so striking and temporarily disabling as to have been called to our attention before this, if it has occurred in our group of patients.

Read before the Section on Nervous and Mental Diseases at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

The syndrome under discussion in many respects is similar to that described by Guillain, Barré and Strohl⁵ and is generally known as the Guillain-Barré syndrome. They describe it as a syndrome characterized by motor disturbances, loss of tendon jerks with preservation of cutaneous reflexes, paresthesias with slight disturbances of objective sensitivity, tenderness on pressure of the muscles, little changes in the electrical reaction of nerve or muscles, and noteworthy hyperalbuminosis of the cerebrospinal fluid in the absence of cytologic reaction (albuminocytologic dissociation).

REPORT OF CASES

CASE 1.—B. S., a girl aged 17 years, was admitted to the Rochester Municipal Hospital on June 20, 1938, because of lower abdominal pain and a vaginal discharge of three months' duration. A diagnosis of gonorrheal cervicitis was made at a local hospital and she received 38 Gm. of sulfanilamide between April 6 and April 10, 1938. Cervical cultures for *Neisseria gonorrhoeae* were positive following the course of sulfanilamide, and she was referred to this hospital for fever therapy.

The patient was well developed and well nourished. Vital signs were normal. The general physical examination was negative, except for some erosion of the cervix and a thick purulent vaginal discharge. Neurologic examination was negative.

Examination of the blood revealed 5,100,000 red blood cells, hemoglobin content 85 per cent, white cells 12,000. The Kahn and Wassermann tests were negative. The nonprotein nitrogen was 27 mg. per hundred cubic centimeters, icterus index 6, blood chlorides (under oil) 626 mg. per hundred cubic centimeters. Cervical cultures revealed *Neisseria gonorrhoeae* with a thermal death time of twenty hours at 41.5 C.

After the routine preparation for fever therapy on June 24 she was given fifteen hours of fever at 41.5 C. with a vaginal heater at 43.5 in situ for eight hours. She tolerated the procedure well except for postfever nausea and vomiting (chloride deprivation). On the second day following fever she became clinically icteric and had an icterus index of 20. On June 26 she was given an infusion of 1,000 cc. of 5 per cent dextrose solution into both thighs. Following this her recovery was uneventful. Three successive cervical cultures were negative prior to her discharge from the hospital on July 1.

The patient returned to the clinic on July 5 complaining of pain and soreness of both thighs. The temperature and pulse were normal. Both thighs were tender, swollen and indurated. A diagnosis of thrombophlebitis was made. The swelling and tenderness promptly subsided with rest in bed and she was discharged four days later.

On August 13 she was admitted to the hospital because of difficulty in walking. This symptom had been first noticed following her last discharge from the hospital on July 9. Associated with the disturbance of gait, which frequently caused her to fall, she had sharp shooting pains which radiated down both lower extremities. There was no history of sphincter or sensory disturbance.

On examination the cranial nerves were normal. Neurologic survey of the upper extremities was negative. The abdominal reflexes were present. The lower extremities were weak. She was able to walk unassisted, but the gait was waddling and unsteady. The calf muscles were flabby and one observer noted fibrillary tremors in the thigh muscles. The knee jerks were normal and the achilles reflexes diminished. There was no sensory disturbance. The plantar reflex was flexion on both sides. There were no abnormal physical manifestations.

A lumbar puncture on August 16 yielded a clear, colorless fluid under pressure of 190 mm. of water. The Queckenstedt test was negative. The fluid contained 4 cells per cubic millimeter. Total protein was 170 mg. per hundred cubic centimeters.

5. Guillain, Georges; Barré, J. A., and Strohl, A.: Sur un syndrome de radiculoneurite avec peralduminose du liquide céphalo-rachidien sans réaction cellulaire: Remarque sur les caractères cliniques et graphiques des réflexes tendineux, *Bull. et mém. Soc. méd. d. hôp. de Paris* 40: 1462 (Oct. 13) 1916.

The Wassermann reaction and gold curve were negative. On September 10 the spinal fluid was normal except for a total protein content of 140 mg. per hundred cubic centimeters. The spinal fluid at the time of the last puncture on November 21 was normal. The total protein content was 45 mg. per hundred cubic centimeters. The examination of the patient in December 1939 revealed no abnormalities.

CASE 2.—M. P., a man aged 34, was admitted to Strong Memorial Hospital on Nov. 8, 1938, because of a persistent urethral discharge. In 1936 the patient contracted an anterior urethritis, which gradually cleared up with local treatments given over a period of nine months. Two months before admission, one week following exposure, he again noted a profuse urethral discharge. During October he received 63 Gm. of sulfanilamide, 50 cc. of azosulfamide intramuscularly, and seven five hour fever treatments at another institution, without any decrease in the amount of the urethral discharge. He was then referred to this hospital for generalized hyperthermia.

The patient was well developed. The physical examination was negative except for the profuse urethral discharge. There were no abnormal neurologic symptoms or signs.

Examination of the blood revealed a moderate normocytic anemia. The hemoglobin was 10.8 Gm., red blood cells 3,090,000 per cubic millimeter, white blood cells 9,000. Blood chemistry was within normal limits. The Wassermann and Kahn tests on the blood were negative. The gonorrhea complement fixation test was plus-minus. Gonococci were cultured from the first specimen of voided urine. The thermal death time for the strain isolated was in excess of twenty-three hours at 41.5 C.

On November 11 he was given fifteen hours of fever therapy at 41.5 C. He tolerated the procedure well and without any postfever reaction or change in the blood chemistry. Three successive urethral cultures were negative for *Neisseria gonorrhoeae* and he was discharged on November 15.

The patient returned to the hospital on December 4 complaining of weakness and stiffness of the legs. These symptoms began twelve days after the hyperthermia. Associated with the weakness there were mild paresthesias of the legs and hyperhidrosis of the feet. He had no symptoms referable to the cranial nerves, upper extremities or sphincters. The general physical examination showed no abnormalities of the cranial nerves or upper extremities. There was weakness of both legs, particularly the flexors of the thighs and dorsiflexors of the feet. The gait was rather characteristic of that seen in progressive muscular dystrophy. He had difficulty in climbing stairs and he was unable to stand on his toes. The knee reflexes were present but diminished. The left achilles reflex was not definitely elicited and the right was greatly diminished. Tactile and thermal sensations were diminished over the feet and lower half of the legs. Vibration sensation was diminished over the malleoli but postural sensation of the toes was normal. There was excessive perspiration of the feet. The calf muscles were tender to palpation. A lumbar puncture yielded a clear, colorless spinal fluid under pressure of 110 mm. of water. The Queckenstedt test was normal. The fluid contained 4 cells per cubic millimeter and the total protein was 160 mg. per hundred cubic centimeters. Blood and spinal fluid Wassermann tests were negative. The colloidal gold curve was 0000121000. The patient was discharged from the hospital on December 6.

The patient returned to the hospital on December 22 and reported considerable improvement in gait and muscle power. The neurologic signs remained unchanged. A second lumbar puncture yielded a normal spinal fluid except for a total protein content of 110 mg. per hundred cubic centimeters. Further follow-up on this case was impossible, since the patient left the country at this time.

CASE 3.—F. S., a youth aged 18, was admitted to the Rochester Municipal Hospital on Feb. 11, 1939, because of sore throat, rash and a penile lesion. Six weeks before admission he was exposed to syphilis and two weeks following this exposure he developed a hard, painless, ulcerative lesion of the glans penis. The penile lesion began to heal after a period of about three weeks and at about this time he developed a macular eruption over the trunk and upper extremities. Three days before admission he developed a severe sore throat and pain in the

right ear. It was for relief of the latter symptoms that he sought medical aid. The past history was irrelevant.

On examination the patient was found to be in considerable discomfort, the result of the ear pain and sore throat. The temperature was 37.7 C. (99.8 F.) and the pulse 92. The pharynx was injected and edematous. There were bulging and redness of the right ear drum. A maculopapular eruption was present over the trunk and upper extremities. There was generalized shotty lymphadenopathy. A typical chancre in the process of healing was present on the glans penis. Examination of the heart, lungs and abdomen were negative.

Laboratory examination of the blood revealed 5,080,000 red blood cells per cubic millimeter and 8,100 white blood cells, with a normal differential count. The urine and stool examinations gave negative results. The blood Wassermann and Kahn tests were 4 plus. Dark field examinations of material obtained from the penile lesion revealed *Spirochaeta pallida*.

On February 14 the patient was given fifteen hours of fever therapy at 41.4 C., which he tolerated very well. Dark field examinations of scrapings from the penile lesion on February 15, 16, 17 and 20 were negative for *Spirochaeta pallida*. Chemotherapy was started on February 25 and the patient received one injection of arsphenamine, two injections of neoarsphenamine and three injections of mercuric succinimide before his discharge from the hospital on March 2. At the time of discharge his blood Wassermann test was 4 plus in 1:32 dilution. The primary and secondary manifestations of syphilis had completely disappeared.

He was given 0.4 Gm. of arsphenamine on March 4. One week later, when he returned for his next treatment, he complained of pain across the lower part of the back, cramps in his legs and difficulty in walking. The onset of these symptoms apparently occurred immediately after his discharge from the hospital on March 2. A lumbar puncture done on March 14 yielded a clear, colorless spinal fluid under normal pressure. There were no cells in the spinal fluid, but the total protein content was 160 mg. per hundred cubic centimeters. The Wassermann test reported on the spinal fluid was noncholesterinized antigen \pm , cholesterinized antigen 3+, Kahn test —. The colloidal gold test showed no abnormality.

The patient was referred to the Neurological Clinic on March 15. He complained of difficulty in walking, pains in the legs and excessive perspiration of the feet. These symptoms had developed seventeen days after the fever treatment. There were no symptoms referable to the cranial nerves, upper extremities or sphincters. The patient walked, unaided, with a waddling, steppage type of gait. There was marked weakness of the flexors and extensors of both feet. He was unable to elevate the heels more than an inch from the floor when attempting to stand on his toes. The pelvic girdles and thigh muscles showed some slight weakness. There was no localized atrophy or fibrillary tremors observed in the musculature of the lower extremities. The lower tendon reflexes were hyperactive and equal. The Babinski sign could not be elicited. Deep and superficial sensations were normal. There was marked hyperhidrosis of the feet.

The patient was seen in the Neurology Clinic one month later, on April 15. He reported considerable improvement in the strength of the lower extremities but he was still unable to walk long distances without fatigue. The gait showed considerable improvement and the muscular weakness was less marked than formerly. There was the same tenderness on palpation of the popliteal spaces and also on the lateral aspects of the legs over the peroneal nerves. The tendon reflexes were still hyperactive.

A lumbar puncture done on April 22 yielded a normal spinal fluid, except for total protein content of 120 mg. per hundred cubic centimeters. The spinal fluid Wassermann and Kahn tests were negative.

On May 20 the patient reported some improvement in the motor power of the lower extremities but the gait was still abnormal. He was seen again in December 1939, and at this time the gait was normal. Reexamination in April 1940 revealed no abnormalities. The total protein content of the spinal fluid was 35 mg. per hundred cubic centimeters.

CASE 4.—J. A., a man aged 24, was admitted to the Rochester Municipal Hospital on April 14, 1939, with a diagnosis of chronic myelogenous leukemia. The disease began thirteen months before admission with hemorrhage from the gums following the extraction of several teeth. He had been treated with solution of potassium arsenite at intervals in an effort to keep the white blood cells below 1,000,000 per cubic millimeter. He complained of some numbness and tingling of the hands while taking this medication, but no muscular weakness had been noted.

On examination the patient appeared chronically ill. Vital signs were normal except for a temperature of 38.8 C. (101.8 F.). The skin showed some brownish pigmentation. There was marked enlargement of the spleen and liver. Blood studies showed a moderate normocytic hyperchromic anemia and the white blood cell count was 207,600 cells per cubic millimeter. The blood smear was typical of myeloid leukemia. The neurologic examination was negative except for loss of the achilles reflexes. The patient was given a course of high voltage roentgen therapy which resulted in decrease in the size of the spleen and reduction of the white blood cells to 75,000 per cubic millimeter. He was then discharged from the hospital on May 12 and was followed in the Blood Clinic.

On October 31 he complained of a penile lesion which had been present for about one month. Examination revealed two superficial lesions without induration of the glans penis. Dark field examination of material obtained from these lesions revealed numerous spirochetes. Blood Wassermann and Kahn tests taken at this time were negative. There were no secondary manifestations of syphilis.

The patient was readmitted to the hospital and after the routine preparation he was given fifteen hours of hyperthermia at 41.5 C. on November 6. The white blood cell count at the beginning of treatment was 119,000 and at the conclusion 120,000. No spirochetes could be found on dark field examination after five hours of fever. On November 9 the dark field examination was still negative for spirochetes. At the time of discharge, November 14, the penile lesion had healed, there were no secondary lesions and the blood Wassermann test was negative. The white blood cell count was 318,000 per cubic millimeter.

The patient returned to the clinic on November 22 complaining of sharp pains in his lower back and legs, weakness of the legs, difficulty in walking and numbness of his feet. These symptoms began eleven days following the fever treatment. The weakness of the legs was so marked that he could not climb stairs or walk on level ground without some assistance. There was no sphincter disturbance. The pains in his back and legs were increased by such acts as coughing, sneezing and straining. The abnormal neurologic signs were limited to the lower extremities. The lower tendon reflexes were absent. All muscle groups in the lower extremities were weak. He was unable to rise on his toes. His gait was waddling in type and very unsteady. The manner of arising from the recumbent position was similar to that observed in progressive muscular dystrophy. There was diminution of pain and temperature sensation over the lower third of the legs and feet, of patchy distribution. There were no pyramidal tract signs. Spinal fluid examination on November 22 was normal except for a total protein content of 79 mg. per hundred cubic centimeters. Subsequent lumbar punctures revealed total protein values as follows: December 3, 140 mg.; December 21, 130 mg.; April 26, 1940, 50 mg. At the time of his last examination, April 26, he was greatly improved although there was still some evidence of muscular weakness. The neurologic examination was negative except for absence of the achilles reflex.

CASE 5.—C. S., a woman aged 26, was admitted to Strong Memorial Hospital on Oct. 9, 1939, because of a vaginal discharge and lower abdominal pain. Four months before admission she acquired a gonococcal infection and since this time she had taken 500 Gm. or more of sulfanilamide without any improvement in her symptoms.

The patient was undernourished. Vital signs were normal. The physical examination was negative except for tenderness in both lower quadrants and erosion of the cervix and the vaginal discharge. The neurologic examination was negative.

Examination of the blood revealed 4,400,000 red blood cells, hemoglobin 12 Gm., white cells 14,100. Blood sulfanilamide was 7.5 mg. per hundred cubic centimeters. Gonococci were cultured from both the urethra and the cervix. The blood Wassermann test was negative. Urine examination was negative.

The patient was given 33 Gm. of sulfapyridine between October 13 and 21. The blood sulfapyridine content on October 18 was 5.8 mg. per hundred cubic centimeters. Cervical and urethral cultures taken two days after the sulfapyridine was discontinued were still positive for gonococci. In view of the unsatisfactory results of sulfonamide therapy, it was decided to give her fever therapy.

On October 30, after routine preparation, she was given fifteen hours of hyperthermia at 41.5 C. She withstood this procedure very well except for persistent vomiting. Cervical and urethral cultures taken on November 1, 2, 3 and 6 were negative for gonococci. She was discharged on November 6, free from symptoms.

The patient returned to the hospital on November 24 complaining of numbness and weakness of her legs and feet. These symptoms had appeared two weeks after fever treatment and were accompanied by severe pains in her lower back and legs, but they did not prevent her from working. The neurologic examination was negative, except for loss of the achilles reflexes, weakness of the legs and feet and unsteadiness of gait. There were no sensory changes. She returned two weeks later for lumbar puncture. The spinal fluid showed a positive Pandy test and no cells. The total protein was 240 mg. per hundred cubic centimeters.

At the time of her last examination, April 1, complete recovery had taken place and the total protein content of the spinal fluid was 30 mg. per hundred cubic centimeters.

CASE 6.—L. A., a man aged 46, was admitted to the Strong Memorial Hospital on Jan. 2, 1940, for treatment of tabes dorsalis with fever therapy. He gave a history of a penile lesion in 1924, which was treated with mercury inunctions and some medication by mouth over a period of three months. During the past four years he complained of sharp shooting pains in his legs, difficulty in starting the urinary stream, and incontinence of the urine at night. He had noted no disturbances of gait.

The neurologic examination was negative except for unequal pupils, which reacted poorly to light and in accommodation. The tendon reflexes were normal and there was no disturbance of deep or superficial sensibility. Physical examination was not remarkable.

Examination of the blood revealed 12.8 Gm. of hemoglobin, 3,950,000 red blood cells per cubic millimeter and 11,400 white blood cells. The differential count was normal. Urine and stool examinations were negative. The blood Wassermann test with both antigens and the Kahn test were 4 plus. Lumbar puncture yielded a clear, colorless fluid under normal pressure. There were 10 lymphocytes per cubic millimeter. The total protein content of the spinal fluid was 45 mg. per hundred cubic centimeters.

On January 5 he was given fifteen hours of fever at 41.5 + C. without complications. Following the fever treatment he was up and about the division and was discharged January 10.

He returned to the clinic February 9 complaining of weakness of his legs and difficulty in walking. The onset of his weakness was noted following his discharge from the hospital January 10. Over a period of three or four days the weakness rapidly progressed to a point where he was hardly able to walk, unable to climb stairs and unable to get out of a chair without helping himself with his arms, and it was impossible for him to stand on his toes. At no time was there severe pain in his back or legs. Paresthesias were present over the lower legs and feet.

The neurologic examination at this visit was the same as previously recorded except for absence of the right achilles reflex and diminution of the left. He walked with a waddling type of gait. He was unable to get out of a chair without helping himself with his upper extremities. It was impossible for him to climb stairs. Spinal fluid was obtained at the time of this examination, which showed 2 lymphocytes per cubic millimeter and a total protein content of 100 mg. per hundred cubic centimeters.

At the time of his last examination, May 11, there was considerable improvement in the muscular weakness of the lower extremities. The gait was practically normal. The achilles reflexes were absent. Total protein content of the spinal fluid was 45 mg. per hundred cubic centimeters.

Another case which came under observation recently might be briefly mentioned at this time:

A man aged 36 was seen in consultation because of weakness of the legs. His illness began two months previously with pains and tingling sensations in his legs. These symptoms were followed by progressive weakness of his legs which made walking difficult and climbing stairs almost impossible. There was no history of a febrile illness or ingestion of drugs prior to the onset of the neurologic symptoms.

Examination revealed marked weakness of the musculature of the lower extremities without atrophy. He was able to walk unassisted, but climbing stairs was difficult and he was unable to elevate the heels from the floor. The lower tendon reflexes were absent. There was no nerve or muscle tenderness and no sensory changes. The only abnormality of the spinal fluid was a total protein value of 200 mg. per hundred cubic centimeters. This case presented the same clinical picture as the cases already described and is regarded by us as a spontaneous case of the syndrome under discussion.

COMMENT

The six cases reported can be summarized together from the time the fever treatments were given. Each patient was given fifteen hours of fever at 41.5 C. without any unusual complication at the time of treatment or immediately thereafter. In each case there developed within a period of from ten to sixteen days (except in case 6) following fever treatment a neurologic syndrome, unaccompanied by fever, which was remarkably constant. The most constant feature was motor disturbances involving the muscles of the pelvic girdle and lower extremities resulting in a waddling type of gait which was not unlike that seen in progressive muscular dystrophy. Severe radicular pains, muscle nerve tenderness and mild dyesthesias occurred in several of the cases. In no instance were there symptoms referable to the cranial nerves or sphincters. The positive neurologic signs in all cases were limited to the lower half of the body and consisted of muscular weakness resulting in a waddling gait, diminution or absence of the tendon reflexes, minimal disturbances of deep and superficial sensation, and nerve tenderness. Three of the patients complained of marked hyperhidrosis of the feet. Spinal fluid examination in six cases yielded a normal spinal fluid except for an increase in the total protein content ranging between 100 and 240 mg. per hundred cubic centimeters without any increase in the number of cells.

The analysis of these cases, aside from the similarity of the neurologic syndrome, reveals two common factors: first, a prolonged fever treatment of fifteen hours at 41.5 C. and, second, the onset of the neurologic symptoms at a definite time interval ranging between eleven and sixteen days after the treatment. Three patients in the series had taken fairly large amounts of sulfanilamide or its derivatives without evidence of toxic manifestations which could be attributed to the drug or the disease. The drug in case 1 had been discontinued for eight weeks before fever treatment was given. In case 2 it had been stopped two weeks before, and in case 5 it was discontinued a few days before fever therapy was given. Two patients had primary syphilis but only one showed a weakly positive spinal fluid Wassermann reaction for five weeks.

About the time at which we encountered the second case a somewhat similar one was reported by Ornsteen and Furst. Their patient had received about 130 Gm. of sulfanilamide over a period of about thirty-five days for the treatment of gonorrheal infection. About two weeks after the drug was discontinued he was given approximately four hours of fever therapy between 106 and 107 F. He felt much improved and gained weight until one month later, when he noticed that his hips and legs were growing increasingly weaker. He did not complain of pain in his limbs but did note patchy numbness and paresthesia. The chief neurologic signs were waddling gait, weakness of the dorsiflexors of the left foot, loss of the abdominal and left cremasteric reflex, absent achilles reflexes, hypo-active knee jerks, tenderness of muscles, and normal sensation with the exception of diminution of pin point perception below the middle third of the legs. Sulfanilamide was not detected in the blood. Examination of the spinal fluid was essentially negative. The patient left the hospital greatly improved one month after his admission because of the neurologic disorder. They concluded that this was a case of toxic neuritis with a progressive muscular dystrophy-like picture probably resulting from excessive ingestion of sulfanilamide.

The case described by Ornsteen and Furst and our cases 1, 2 and 5 were similar in many respects. The fact that fairly large amounts of sulfanilamide had been administered in these three cases made it seem logical to conclude that the drug alone, or its use prior to the fever treatment, was in some way responsible for the neurologic changes.

Prior to the advent of sulfanilamide and with routine fifteen hour treatments, a neurologic complication of the type described has not been observed in our clinic, where various amounts of fever at high temperatures have been administered in 1,100 cases. The follow-up on all of these 1,100 cases has been adequate enough to warrant the belief that no similar cases have resulted from the technic of the treatment. In recent literature many toxic effects of sulfanilamide have been described, but as a rule they appear during the administration of the drug and subside when it is discontinued. However, cases have been reported in which the toxic manifestations have been delayed. Lockwood⁶ mentioned a case in which severe hemolytic jaundice developed eighteen days after the drug had been discontinued.

In view of the fact that this neurologic syndrome had never been observed to follow either form of treatment when used alone, it was thought that perhaps the combination might in some way be responsible. A few months later, however, following a routine fifteen hour fever, we observed the same syndrome in two cases of primary syphilis and one case of *tabes dorsalis* in which sulfanilamide had never been given. This seemed to exclude sulfanilamide as a causative agent. Likewise the technic of the fever therapy appeared unlikely as the sole cause. In this clinic several hundred cases were treated with prolonged fever, from fifteen to twenty-seven hours at 41.5 C. (106.7 F.), prior to June 1938 without any complication of this type.

Guillain believes that the syndrome which he described is of infectious origin, presumably a neurotropic virus. He also stated that in some cases it had been noted that the polyradiculoneuritic syndrome developed often after a suppurative infection. He was of

the opinion that in such instances a neurotropic virus plays the principal role but acquires its virulence as a result of the primary illness. At least one virus disease, herpes simplex, seems to be activated by the febrile state (Carpenter, Boak and Warren⁷). The herpetic vesicles containing the virus develop in about 60 per cent of all cases in which fever treatment is administered. The lesion starts as an erythematous patch on the face, usually about the nose or mouth, about twenty-four to thirty-six hours after the fever. Within twelve hours a papule develops which becomes a vesicle, then a pustule and finally a dry crust, which falls off in a week or ten days, leaving no scar. Herpes simplex developed in three of the six cases under discussion.

There were several features about our cases which suggested an infectious (virus) etiology. Most important of these was the latent period between the fever therapy and the development of the neurologic symptoms. This period was fairly uniform in the six cases reported and might well represent the incubation period of a virus present in the body which became activated by fever therapy (much as seems to be the case with the herpes simplex virus). We were also impressed by the fact that all the cases were encountered over a period of slightly less than two years, an observation which might indicate that a virus capable of producing the neurologic disorder was prevalent during this time. Additional evidence in favor of this idea is the increase in number of spontaneous cases which we have observed during the same period. These cases differed from those under discussion in that the paralysis was more extensive, the course more protracted and the protein content of the spinal fluid considerably higher. We might regard the cases discussed as mild or abortive forms of the syndrome. In the cases reported, animal inoculations with spinal fluid gave negative results. In 1936 Gilpin, Moersch and Kernohan⁸ reported a large series of cases of polyneuritis with albuminocytologic dissociation and called attention to the increasing incidence of the disorder. It was their impression that the condition was due to a virus that had a predilection for the peripheral neuron.

The prognosis in these cases has been favorable for recovery. Pain and tenderness of the nerves and muscles subsided within a week or two. However, the return of muscular power takes much longer and it is usually from four to six months before the gait returns to normal. The abnormality of the spinal fluid is likewise slow in clearing.

Treatment of these cases consisted of the usual therapy for cases of polyneuritis due to other causes (relief of pain, rest of muscles and so on).

SUMMARY AND CONCLUSIONS

1. Six cases of polyradiculoneuritis with hyperalbuminosis of the spinal fluid followed the use of sulfanilamide and general hyperthermia.

2. Analysis of these cases would seem to eliminate sulfanilamide and hyperthermia per se as the cause of the syndrome.

3. It would seem that the disorder is the result of the activation of some infectious agent, perhaps a virus, by the fever.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. DE JONG AND DRs. GARVEY, JONES
AND WARREN

DR. LOUIS CASAMAJOR, New York: Much confusion has existed concerning the term "Landry's paralysis." It was early believed to be a form of subacute poliomyelitis but later work showed that progressive ascending paralysis was not occasioned by a progressive ascending inflammatory reaction in the anterior central gray matter. The clinical course of these cases with complete recovery of a large majority taught that the lesion was not one of destruction of the anterior horn cells. Obviously some reversible process must exist as the basis of acute ascending paralysis. The pathologic observations which Dr. DeJong reports in his cases were practically identical with those of the two cases I reported in 1919. The differences were of degree and not of kind. I was convinced that the primary lesion was an inflammatory one in the arachnoid affecting primarily the nerve roots where they run in the arachnoid. The peripheral nerve changes and those in the anterior horn and spinal ganglion cells are secondary to interruption of nerve fiber function by the arachnoid inflammation. The situation was somewhat similar to tabes as described by Nageotte and it is interesting that in tabes with a productive arachnoiditis the changes are almost entirely in the sensory roots. In the acute ascending paralysis there is likewise an arachnoiditis but not a productive one, and for some unknown reason the changes are more in the anterior roots. When my cases were reported I was unaware of the article of Guillain-Barré and Stöhl, which had been published three years earlier. Spinal punctures could not be done in my cases as they were observed under conditions of active warfare, and had the spinal fluid been obtained there were no facilities for determination of total protein. In the cases seen more recently the albuminocytologic dissociation described by these authors was present in all. Dr. DeJong included in his paper two cases in which, for good reasons, lumbar puncture was not done. In the second case of his series there was a definite albuminocytologic dissociation. The existence of the high protein and low cell count in the spinal fluid is to my mind a valuable finding. I feel it is the spinal fluid expression of the inflammatory changes in the arachnoid which I believe to be the basic cause of the condition. The existence of such a reaction differentiates the condition from poliomyelitis on the one hand and peripheral neuritis on the other. Were this a real anterior horn cell degeneration due to poliomyelitis, one would certainly expect to find the meningeal reaction which gives the increase of cells with not such a great increase of protein. That fact alone proves that the pathologic change responsible for this condition exists inside the dural sac. The term "Landry's paralysis" could be dropped without much loss to our nomenclature.

DR. PETER BASSOE, Chicago: I wish Dr. De Jong had taken more time to describe that type of lesion. It perhaps represents a clinical entity which we will understand better when we know more about viruses. When it comes to his discussion of terminology, I cannot follow him. The term "Landry's paralysis" is obsolete and confusing, whether Landry's case was one of beriberi, as claimed by Dr. Madelaine Brown, or a cord infection similar to the one described by Dr. De Jong. The term "acute ascending paralysis" (ascending must mean ascending, whether one thing or another; we can't change the English language) is useful as designating a syndrome which is fairly common on account of the segmented structure of the cord. Any disease starting in the lower part of the cord with sufficient momentum to travel upward may produce an ascending paralysis, and I don't see any reason why we should not call it all ascending paralysis, which of course makes it a syndrome only. And I don't see why we shouldn't say that, when ascending paralysis is caused by poliomyelitis, that is also ascending paralysis. Less common are the kinds of myelitis described by Dr. DeJong today. Perhaps they are commoner than we think. Then there are the kinds of spinal root and ganglion inflammation that have been described by Pette and Környey and more recently by Peters and Scheid. Rabies, rabies vaccine paralysis and tick paralysis may be acute ascending; and we may have ascending leptomenigeal,

dural and epidural inflammations and so on. The day I left home I saw for the first time Wilson's magnificent two volume textbook. I looked up what he said about Landry's paralysis, and as most of you may not yet have seen the book I will quote some of his statements: "As a technical term Landry's paralysis lacks precision, etiological or pathological, and its clinical worth is a little dubious. The name lingers on, none the less, bearing witness to the fact that clinical types of acute ascending paralysis are not uncommon and that knowledge of their causation is still at times rudimentary." Wilson considers it a mistake to confine the syndrome to the motor system. He included poliomyelitis, also ascending myelitis, in the spinal disorders. He says "As has often happened in medicine, the first conception has been widened and a host of cases included of which perhaps only a few strictly conform to it. On the pathologic side, too, variations have been numerous enough to render a unitary acute ascending paralysis impossible." Then finally he adds something pertinent to what Dr. De Jong has said today, namely "For some obscure reason several writers today seek to restrict Landry's paralysis to the acute ascending toxicosis of ventral horn cells" (without inflammation).

DR. A. M. ORNSTEEN, Philadelphia: In the group of cases reported by Dr. Garvey and his co-workers there can be no question about its similarity to the Guillain-Barré syndrome because of the acute onset with a uniformity of clinical picture as he described involving the lower extremities and the cytoalbumin dissociation which has been consistently held as a differential finding in this form of multiple or polyneuritis. In an experience of 1,150 cases of fever therapy, given I presume under similarly controlled conditions over a period of ten years, Dr. Garvey and his co-workers have not seen such a complication, but in the past two years they have seen six cases under identical conditions of the fever treatment with a period of incubation of from ten to sixteen days, followed by weakness of both lower limbs, pain in the back, severe in some cases, various reflex and sensory changes and with the spinal fluid feature already mentioned. They did not conclude that fever therapy was the cause of it; neither could they conclude that sulfanilamide would produce the neuritis, for obvious reasons, and their conclusion that the virus was activated by fever I believe is acceptable unless some one can give a reason why such a situation does not occur occasionally in the situation in which patients harbor a virus and their resistance to that virus is altered by certain physical factors. It has been well known that neuritis is often attributed by the patient and the physician to a certain physical factor, exposure frequently the offending factor; and there are people who still believe that such a common peripheral neuritis as Bell's palsy is caused by exposure, whereas others believe that the particular individual who develops a Bell's palsy must have some factor in the background which makes that nerve vulnerable to exposure; hence Dr. Garvey's interpretation that activation of a virus in the host may be produced under certain conditions, at present not understood, by fever. Since it did not happen in the first eight years of the decade of his survey and it has in the last two years, it would be interesting to determine whether or not in his community there were an equal number of cases, not just the one other case which he saw in which no sulfanilamide or fever therapy was given, that showed a development of the Guillain-Barré syndrome. That would be more convincing; the increased incidence of the disease would explain the increased number of carriers of the virus and, under certain conditions, such as hyperpyrexia in Dr. Garvey's cases, exposure to cold, or a background of vitamin deficiency, infectious polyneuritis may be precipitated.

DR. FREDERICK P. MOERSCH, Rochester, Minn.: We have more or less dropped the term "Landry's paralysis" because we do not know the etiology of the condition. Once we discover the exact etiology of "Landry's paralysis" a reclassification of these conditions will be easier. As far as I know, we have seen no case of peripheral neuritis or polyradiculoneuritis resulting from sulfanilamide therapy. We have observed cases of peripheral neuritis resulting from preparations related to sulfanilamide. The fact that neurologic complications so rarely follow the use of sulfanilamide I believe is good evidence that in Dr. Garvey's cases the sulfanilamide

probably had no relation to the onset of the symptoms. Regarding fever therapy, we have observed one instance of polyradiculoneuritis following from therapy. It was interesting that this patient, because of an acne, had received a preparation containing tin just prior to the fever therapy and sulfanilamide. We were unable to determine in our own minds whether the neuritis or polyneuritis was due to tin, to fever or to some unknown factor. Some time later when we went through what seemed to be a wave of polyradiculoneuritis we instituted fever therapy in these cases with poor results, and we concluded that fever therapy in cases of polyneuritis was rather harmful. Dr. Krusen of our staff has called to my attention a report by Dr. Gwynn of Washington, who reported four cases of peripheral neuritis following fever therapy. At the same time, in the same city but in another hospital, and using a little different type of fever therapy, there were observed fourteen cases of peripheral neuritis following fever therapy. I have seen the records of some of those patients and I am inclined to believe that they represent a polyradiculoneuritis as described by Dr. Garvey and his co-workers. The large number of cases of peripheral neuritis occurring in one locality suggests the possibility of some infectious basis. As noted by Dr. Garvey, the usual sequence of events in a case of polyradiculoneuritis is an infection, a latent period, and then the development of a polyradiculoneuritis, suggesting the presence of a common denominator as a virus. There are many cases in which no infection or infectious history is obtainable, and I have been wondering whether polyradiculoneuritis may not after all be another syndrome rather than a disease entity resulting from a specific virus.

DR. A. E. BENNETT, Omaha: I should like to inject into this discussion of cases involving the so-called Landry syndrome the possibility that some of them resemble curare poisoning. Of the cases I have seen, an almost pure flaccid motor paralysis develops in most and death occurs from asphyxia. However, when recovery occurs it is rapid. In one recent case recovery occurred within a few days after the paralysis became complete, including the respiratory muscles. Prostigmine and thiamine were used in treatment. It seems that there is some evidence to show that perhaps faulty neuromuscular function with a lack of acetylcholine may be a factor in this syndrome. With respect to Dr. Garvey's cases, almost any clinic that has given large numbers of fever therapy treatments has seen this complication. Dr. Garvey's patients were given long fever therapy heatings of ten hours or more. I doubt the idea of virus infection being responsible for this disorder. Anoxia and thiamine deficiency are more likely causative factors. Weaver, formerly of Ohio State and now of Detroit, has definitely produced peripheral neuritis in animals with fever therapy and anoxia. Since we discovered this condition we have given all our patients prophylactically large doses of thiamine and throughout the long heatings they get oxygen. As Dr. Moersch told you, in the large number of treatments given at the Mayo Clinic they have seen only one case, and it has been routine for Dr. Krusen to use continuous oxygen inhalation with fever therapy. It may be that sulfanilamide is also a factor in the production of anoxia and finally polyneuritis.

DR. NORMAN JOLLIFFE, New York: I should like to bring out a point that may account for the development of polyneuropathy following fever therapy. It was shown several years ago by Cowgill that the vitamin B₁ requirement increased with an increase in total metabolism. The administration of fever therapy over a period of ten hours every day or every other day must increase the total metabolism markedly, and with it a parallel rise in the thiamine hydrochloride requirement. It would not be inconceivable that the vitamin B₁ requirement of these individuals was doubled, and unless dietary precautions were taken to increase the B vitamins it is likely that with the increased requirement due to fever therapy their diet was inadequate in vitamin B₁. The ten to fourteen day period mentioned by Dr. Garvey could as well be the time required to develop a polyneuropathy due to a vitamin B₁ deficiency as to an incubation period of an infection. I should like to ask a question concerning the cell counts in Dr. Garvey's patients. I believe that in about one half of his patients

absolutely no cells were found in the spinal fluid. Did he not mean to indicate that there was no increase in cells?

DR. PAUL C. BUCY, Chicago: Dr. Joliffe, I should like to ask whether or not you would expect this alteration in protein content in the spinal fluid with thiamine hydrochloride deficiency?

DR. JOLLIFFE: Certainly not, as a rule. We have, however, seen increased protein in the spinal fluid in patients having thiamine hydrochloride deficiency, though it occurs rarely. Whether the increased protein was due to B₁ deficiency or not, I have no proof. Since thiamine hydrochloride deficiency is not limited to the peripheral nerves but includes changes in the roots and spinal columns as well, it is theoretically possible that an increased protein content might result from thiamine hydrochloride deficiency.

DR. MOERSCH: In a postdiphtheritic polyneuritis in which there is an increase in the total protein, would that fit in with this? I was wondering what your experience might be.

DR. JOLLIFFE: I have never seen an acute postdiphtheritic neuritis, but it would fit in with this explanation.

DR. IRVING J. SANDS, Brooklyn: Those of us who have had the opportunity of following the various types of encephalitis during the past years have been impressed with the increase in the number of patients of the type described by the readers of the last two papers. Dr. De Jong's cases brought to my attention a group of patients we have had the privilege of following in Dr. Riley's division at the Neurological Institute. They have been described as diseases due to virus infection, manifested clinically by an ascending type of paralysis. Those cases which came to necropsy showed a difference in the pathologic condition though clinically they showed an almost identical course. I recall two patients who had a definite ascending paralysis with death resulting in about six to ten days after the onset of the illness. In one patient multiple areas of demyelination were found, and in the other nothing except slight cloudy swelling and chromatolysis were detected. During the past four years I have had the opportunity of following a group of cases at the Kingston Avenue Hospital for Contagious Diseases. They presented a symptomatology as shown by Dr. Garvey's patients. However, they had a much larger total protein in the spinal fluid, usually between 200 and 350 mm. In the majority of these cases there was a history of a mild upper respiratory infection preceding the onset of the neurologic signs. In the past two years we have been giving them large doses of thiamine hydrochloride. It has been my impression that thiamine hydrochloride therapy has made no difference in the speed or the extent of the recovery. What is the etiology of these cases? I believe that it is due to a virus infection, though I have no definite proof. It is the opinion of many who have studied the manifestations of encephalitis and encephalomyelitis that the virus agents comprise a large group like the pneumococci, that eventually these different groups will be differentiated and recognized, and that each type of virus will be proved to have a special predilection for invasion of a particular part of the nervous system producing the different clinical types of neurologic disorders with which we are now familiar clinically.

DR. DONALD SHASKAN, New York: In a period of less than two years we have followed eight cases of the Guillain-Barré syndrome in Dr. Foster Kennedy's service at Bellevue. I should like to ask Dr. Garvey two questions: Guillain has stipulated that from 1,000 to 2,000 mg. of total protein was necessary for the diagnosis of this syndrome, and I wondered what Dr. Garvey thinks of this quantitative differentiation as a factor in diagnosis. The second question is Why should no virus have been recovered in any of these cases, either Dr. Garvey's cases or any cases in the literature?

DR. A. M. RABNER, Brooklyn: I had not intended discussing these cases until some of the discussers attempted to blame fever therapy for the development of these clinical syndromes. On a number of occasions spinal fluid examinations of patients who did not have any evidences of polyneuritis, polyradiculoneuritis or meningo-encephalomyelitis, who in the course of an upper respiratory infection seemed somewhat drowsy, had spinal fluid study performed which revealed an

increased total protein. We also know that virus infections causing the so-called common cold produce a varying type of clinical picture. Sometimes there is only a tracheitis, at other times more widespread involvement of the respiratory apparatus. In other words, we know that virus infections that do not involve the central or peripheral nervous system may produce a protean type of implication of the system in general. Some years ago when Dr. Strauss and I reported a group of these cases we called them, for want of a better name, myelodradiculitis. In reviewing the literature we found reports of similar clinical syndromes from all over the world with many names attached to them, indicating varying diffuse anatomic involvement, at times limited to the brain, at other times affecting also the meninges, sometimes limited only to the cord and often implicating all the structures from the peripheral nerves up the roots, to the brain. The names given to these syndromes were usually purely anatomic designations of the structures involved. One of our patients subsequently developed a parkinsonian syndrome and this suggests an etiology similar to that causing epidemic encephalitis. Here then Dr. Garvey reports a group of six cases occurring within a short period of time under the same type of fever therapy regimen that has been given to their patients in previous years. Now for the first time six cases appear with this clinical picture. To blame the fever therapy for this I think is a far fetched speculation. These are undoubtedly cases in which there was a virus infection of the nervous system during the period fever therapy was being administered.

DR. RALPH HAYWARD, Toronto: I want to mention about 150 cases of ascending paralysis that I saw in West China. These cases all seemed to occur in a region of about 20 miles radius. Cities 100 miles away had none at all. The onset was sudden, with a little nausea and vomiting, the symptoms appeared in about five or six hours, and recovery would occur in three or four days. About 5 per cent of the patients died within forty-eight hours. The peculiar thing was that the inhabitants of the city did not seem to be bothered, but after the war with Japan a national university came to our city and the students came down with it in large numbers; I don't know whether it was from eating the same things or from respiratory infection. Just as I came away this April there were several camps for wounded soldiers where the men were coming down in large numbers with this same disease.

DR. RUSSELL N. DE JONG, Ann Arbor, Mich.: It was desirable that my paper on acute ascending paralysis and Dr. Garvey's paper on the Guillain-Barré syndrome be discussed together, because clinically these two conditions are similar and they may represent different stages or degrees of the same disorder. I have been studying a group of cases, seen in the University Hospital in Ann Arbor, which conform closely to those described by Guillain and Barré, but I disagree with the French authors in certain respects. In their terminology of the syndrome they use the word "curable" polyradiculoneuritis. If the syndrome is to be diagnosed by the presence of albuminocytologic dissociation, I am sure that not all cases are curable. I have observed some cases that conformed to the descriptions of Guillain and Barré but had a chronic course and others that terminated fatally. The condition is certainly more than a peripheral neuritis, as in some cases a facial paralysis has been noted, others have shown evidence of a brain stem or bulbar paralysis, and papilledema has been noted in certain instances. Paralysis of the bowels or bladder is not unusual. The cases that terminate fatally are similar to those that I have described today as cases of acute ascending paralysis, and it is my impression that these all are members of the same group of disorders. If that is the case, we shall have to enlarge or broaden our concept of the term "polyradiculoneuritis" as described by Guillain and Barré, noting that the prognosis is not favorable in all cases—not all are curable, and some terminate fatally.

DR. PAUL H. GARVEY, Rochester, N. Y.: In reply to Dr. Ornstein, at the present time we have two patients in the hospital that have total protein contents one of 800 and one of 600, and since this paper was written we have had three more cases following fever therapy. Perhaps this protein is

due to edema and vascular congestion at the time of the fever treatment. However, we have done routine punctures on the last three patients that developed the same syndrome and the total protein content of fluid was within normal limits three days after the treatment, so presumably that abnormality develops later and cannot be directly related to the fever. It was suggested by Dr. Bennett that it was due to anoxia and perhaps to the fever treatment. Prior to two years ago we treated patients for twenty-seven hours and many patients have been treated more than fifteen hours without anything of this sort developing, so that I should think if it were on that basis these cases would have occurred before two years ago. With regard to this being a vitamin deficiency or the development of an acute deficiency, it has been our experience that large doses of thiamine hydrochloride have not been effective in the treatment of these cases. In the neuritis associated with chronic alcoholism, which is a good example of a deficiency neuropathy, the total protein content of the spinal fluid is not appreciably elevated. The cell counts were taken from the records recorded by the house officers. Of course from ten to fifteen years ago a cell count of ten was said to be normal; now we know that anything above five is considered abnormal, so that so far as the chart was concerned I would just as soon have one, two, three or four cells on that chart as none. Guillain in his recent article insists that 1 or 2 Gm. of protein must be present in the spinal fluid in order to make the diagnosis. I think it seldom attains that level. He mentioned in his article that when the spinal fluid protein is lower than 1 or 2 Gm. they must be considered as abortive cases. It is interesting that about two weeks ago in *THE JOURNAL* Stone and Aldrich reported two cases of this syndrome in which albuminocytologic dissociation was a late development.

THE EFFECT OF DISTENTION OF ABDOMINAL VISCERA

ON THE CORONARY BLOOD FLOW AND ON
ANGINA PECTORIS

N. C. GILBERT, M.D.

G. K. FENN, M.D.

AND

G. V. LEROY, M.D.

CHICAGO

The incidence of anginal pain following the ingestion of food has been commented on by most of the writers on angina pectoris, beginning with Heberden,¹ who stated that "those who are afflicted with it are seized while they are walking, and more particularly if they walk soon after eating." Osler,² in his monograph on angina pectoris, states "Of the exciting causes there are three important elements: muscular exertion, mental emotion and digestive disturbances. . . . As an attack ends, the patient may belch quantities of gas or pass flatus from the bowel, both with apparent great relief." So marked is the association of pain with upper digestive tract symptoms that Verdon³ and later the Jacksons⁴ considered that the pain was of neuromuscular origin, consequent on gas under pressure in a hollow viscus.

The increased incidence of anginal pain after meals is explained in part by the increased work required

of the heart during digestion. This of itself demands an increased coronary flow, and the vessels may not be able to supply this demand even without the added factor of exertion. But this does not explain the effect of gaseous distention of the stomach in causing anginal attacks or the relief offered by belching. And it does not explain the influence of abdominal distention.

There is both clinical and experimental evidence to indicate a reflex vasoconstriction of the coronary arteries consequent on some stimulus arising in the viscera or elsewhere. Huchard⁵ predicated a reflex angina, and Daniélopou⁶ considered that a coronary vasoconstriction could result from a stimulus originating in the thoracic cavity. Anrep⁷ showed a reflex decrease in coronary flow with an increase in the intracerephalic pressure, and Stella⁸ showed that this was produced by means of the carotid sinus. Manning, McEachern and Hall⁹ showed that there was a reflex vasoconstriction following sudden occlusion of other coronary branches. De Takats, Beck and Fenn¹⁰ presented evidence indicating a reflex vasoconstriction of coronary arteries following pulmonary embolism. Von Bergmann¹¹ showed a reflex vasoconstriction of the coronary arteries following gastric distention, and Rein¹² showed that there was some constant vagal tone present in the coronary arteries and that constriction resulted from vagus stimulation.

There would seem to be abundant experimental evidence to indicate that stimulation of the vagus does result in vasoconstriction of the coronary vessels. This is amply reviewed by Anrep¹³ and by C. W. Greene.¹⁴ As Greene states, however, the reaction of the coronary vessels to stimulation cannot be predicted because of the close morphologic and physiologic association of the vasoconstrictor and vasodilator pathways. In order to prove the hypothesis of vagal origin of the vasoconstrictor fibers, he performed a series of crucial experiments in which he completely severed the vagal neurons from the coronary vagosympathetic pathways. This he accomplished by sectioning the vagus at its exit from the jugular foramen and carried on a series of physiologic experiments after degeneration of the vagus fibers. Dogs with such section of the vagus showed a loss of coronary constriction on cervical vagal-sympathetic stimulation.

In some earlier work with Prof. C. W. Greene in 1925, one of us had observed a decrease in coronary flow on distention of the stomach or the free abdominal cavity, measuring the flow with a Morovitz cannula. The results were not constant and were not published because of the fear that a factitious element might be present. The work was later repeated by Gilbert and

Fenn with similarly inconclusive results. In both cases, lack of constant results can be ascribed to the type of anesthesia used, to the fact that anesthesia was carried to the point at which reflexes would tend to be abolished, and to too strong a stimulus. The Morovitz cannula method is also not as well adapted to this work as is the Rein thermostromuhr. A change in the relative position of the heart may mechanically cause a decrease in flow.

Hinrichsen and Ivy¹⁵ also were unable to find a vasoconstrictor effect on the coronary artery with visceral stimulation but found it possible to show a vasodilator effect.

A short time ago we¹⁶ reported on some experimental work in dogs which indicated that moderate distention of the stomach could cause a reflex constriction of the coronary arteries. Under light anesthesia a thermostromuhr was applied to the circumflex branch of the left coronary artery. The chest was closed and continuous photographic records were made of the coronary flow, together with blood pressure and pulse readings.

TABLE 1.—Experiments on Visceral Distention

Stomach.....	2	0	1	1

Moderate distention of the stomach caused a decrease in the coronary flow without fall in blood pressure. The decrease was greater when the distention affected primarily the cardiac end of the stomach, as was observed by von Bergmann¹¹ in similar experiments. Section of the vagus or administration of atropine abolished the reflex. Distention of the free abdominal cavity with air also resulted in a decreased coronary flow, which again did not appear after vagus section or atropine. Since these experiments were reported, a similar series of experiments have been made on unanesthetized dogs which had previously had a thermostromuhr attached to the circumflex branch of the coronary artery under aseptic conditions, with perfect recovery. The results were essentially the same.

The results of the distention of the stomach and abdominal cavity in the anesthetized dogs and the results of the distention of the stomach in the unanesthetized dogs before and after the injection of atropine are shown in table 1. The results of the gallbladder experiments are not conclusive as far as they have been carried out. The work will be amplified and reported on later.

In order to extend these observations on gastric distention to patients with angina of effort we had recourse to the method devised by Levy.¹⁷ This method consisted in allowing a patient to breathe an oxygen-poor mixture until pain occurred. It was safe, because at

the first sign of pain 100 per cent oxygen was administered with immediate and complete relief. It was of interest that the patients stated that after a spontaneous attack of angina they felt some depressing effect for hours. However, after these induced attacks, followed at once by oxygen administration, they stated that they felt better than before the attack.

The method as used by us consisted in allowing the patient to breathe 10 per cent oxygen and 90 per cent nitrogen while lying quietly in bed and after a thirty minute rest period. The patient was instructed to indicate the moment he felt his typical anginal pain. The procedure was repeated on successive days until the patient became accustomed to the method and the control pain time became stabilized. After the control

pain time had been determined, the procedure was repeated ten minutes after the ingestion of a moderately large meal and the pain time again recorded. Subsequently the second procedure was repeated after atropine in doses of one-fiftieth grain (0.0013 Gm.) had been injected intramuscularly just preceding the

meal. The period required to produce pain in this instance was recorded. Several determinations of each of these pain times were made.

The patients, three in number, were hospitalized for the several days required for the investigation, were known subjects of anginal pain and were removed from all medication for several days preceding the tests. They were selected from a large group of patients because of the constant character of their angina. All three complained initially that exertion after meals produced pain much sooner than was usual at other times. These three also reported that ingestion of certain foods, such as cabbage, sauerkraut, onions and other indigestible foods, was generally followed by an attack of angina. In all of them the angina, of course, varied in degree, but the more severe attack was of the classic Heberden variety. Each of the patients, prior to entering the hospital for this investigation, had obtained marked relief from his anginal symptoms by the faithful use of theophylline with ethylene diamine in doses of from 0.6 to 1 Gm. daily. On withdrawal of the drug, each of these patients had a prompt recurrence of frequent

anginal pain. The pertinent data relative to the patients are shown in table 2.

The effect of the ingestion of food on the pain time is shown in chart 1.

The control pain time is plotted at 100 per cent, no attention being paid to the actual number of minutes required to produce pain. In a similar manner the pain time following ingestion of food and later following ingestion of food plus atropine is plotted in percentages of the control time. The actual time required to produce pain by the respiration of 10 per cent oxygen and the changes produced by food and atropine were quite different in each patient, and these figures are shown elsewhere (table 4).

Patient 1 (J. B.) found that the pain time following the ingestion of food was 19 per cent less than the control time. That is to say, his tolerance for 10 per cent oxygen was reduced by about one fifth. In a similar way patient 2 (G. L.) showed a reduction of 40 per cent and patient 3 (A. K.) a reduction of 35 per cent. We believe that these results demonstrate that the ingestion of a meal considerably increases the susceptibility to anginal pain in these anginous patients.

The effect of atropine on the pain time following the ingestion of food is shown in chart 2. Atropine

ronary Insufficiency,

lengthened the after meal pain time of patient 1 by 17 per cent. In comparing the pain time after food and atropine with the control time it will be seen that they are nearly the same. Actually the pain time after food and atropine was 5 per cent less than the control time. Atropine increased the after meal pain time of patient 2 by 87 per cent, which was enough to make it 12 per cent greater than the control pain time. Atropine increased the after meal pain time of patient 3 by 93 per cent and brought it up to 24 per cent above the control time.

Chart 3, in which the pain time after food plus atropine is plotted against the pain time after food alone, shows these results in a somewhat more striking fashion. The results would seem to indicate that atropine successfully interferes with the mechanism that increases the susceptibility to anginal pain after meals. It is our belief that this interference is due to inhibition of vasoconstrictor impulses that are mediated through the vagus nerve.

It has been stated¹⁸ that a considerable increase in the coronary flow follows the ingestion of food. In our own laboratory we were unable to observe any appre-

article in which they show an increase of 86 per cent in the intact conscious dog after atropine.

The effect of atropine alone on the low oxygen tolerance in two of the patients who were investigated is shown in chart 4. With patient 1 atropine alone made

Chart 1.—The time each subject tolerated the 10 per cent oxygen inhalation before meals is represented as 100 per cent in the left hand column of each group, labeled a. c. The time the gas mixture was tolerated after meals is represented in the right hand column, marked p. c.

ciable increase in coronary flow within the time limits of these experiments.

The effect of the ingestion of food in varying times up to twenty minutes following the meal is shown in table 3. The occurrence of anginal pain following meals has been explained by many writers as due to the inability of the anatomically damaged vessels to meet this demand and that the anatomic damage was the only factor involved. While this is true in many cases, we believe that in many other cases increased vagal tone, or a vasovagal reflex, as described by Weiss and others, plays an important part in the production of pain. Atropine has long been mentioned as an instrument to increase the coronary flow, but no one has been impressed with the significance of this observation. Essex and his co-workers¹⁸ comment on this in a recent

Chart 2.—The tolerance for 10 per cent oxygen before meals is represented in the left hand column of each group as 100 per cent and is labeled a. c. almost no difference. There was actually a reduction of 3.7 per cent in the pain time after atropine. Reference to table 2 will show that patient 1 was a 70 year old man with hypertension and cardiac enlargement. From the physical examination alone, one would suspect the presence of considerable anatomic change in the heart. This, together with the atropine response shown in chart 4, would indicate that the vagal tone was not as important a factor in the production of pain as with patient 2, whose pain time after atropine was increased

Chart 3.—The tolerance for 10 per cent oxygen after meals is represented as 100 per cent in the left hand one of each group of columns and is labeled p. c. The group of columns with the subscript G. L. represents the following: p. c., tolerance after meals = 100 per cent; p. a. p. c., atropine was given, the meal was eaten and then the test was run; p. c. p. a., the meal was eaten, atropine was given and then the test was run; all the tolerance for 10 per cent oxygen after meals and atropine regardless of the time when the drug was given.

33 per cent. Patient 2 had a very slight elevation of pressure and a normal sized heart, and from the physical examination alone it would be difficult to detect cardiac structural changes. With these data in mind, one

ANGINAL PAIN—GILBERT ET AL.

would suspect a much greater vasoconstrictor element in the anginal attacks of patient 2 and a greater organic element in the anginal attacks of patient 1. If this were true, one would forecast the more profound effect that the ingestion of food would have on patient 2 and a greater response from atropine after a meal. That this

We do not need to be convinced that the xanthine bodies increase the coronary flow. Our belief in the efficiency of theobromine and theophylline has been a matter of record for several years. In addition to this, Levy¹⁷ and his associates have already used this method to show the increase in pain time caused by the administration of these drugs. In order to compare the effect of atropine and theophylline on the same patient under the same conditions, an additional experiment was done.

We show in chart 5 that a result in the same direction may be obtained in the first instance by a vagal inhibitor and in the second instance by a coronary vasodilator. As might be expected, the active coronary vasodilator had the more marked effect. The result shown in chart 5 was the effect of a single injection of 0.5 Gm. of theophylline with ethylene diamine. When this patient had taken orally 0.6 Gm. of the drug daily for three days it was impossible to produce pain by the respiration of 10 per cent oxygen for thirteen minutes longer than the control pain time.

COMMENT

Our experiments would seem to indicate quite definitely that the coronary flow in the dog may be reduced by distention of the stomach or abdominal cavity. The results are quite constant if proper attention is paid to anesthesia and the dog is maintained in relatively good condition. In view of the fact that this reduction in flow does not occur after vagal section or after the administration of atropine, it is difficult to escape the conclusion that the reduction in flow is the result of activity of the vagus nerve. This, then, is an instance of reflex coronary vasoconstriction initiated by vagal irritation in the gastrointestinal tract. Attention has been directed to the results of other workers who have brought out evidence indicating the occurrence of a similar reflex coronary vasoconstriction initiated in the lung¹⁰ and in the heart itself.⁹ We feel that similar effects may result from irritation of the gallbladder or biliary tract, and we hope to report later on further experimental work. It would seem quite likely that such vasoconstrictor reflexes might also originate elsewhere in the viscera, but definite proof is lacking. If it is assumed that reflex coronary vasoconstriction may be the result of gastric or abdominal distention, the incidence of anginal pain following meals is explained in part.

In an effort to examine this hypothesis with patients having angina of effort, such patients were subjected to a pain-stimulating mechanism. They were made to breathe 10 per cent oxygen until the pain appeared and it was found that the time required to produce pain in a given patient was remarkably constant from test to test. This induced pain appeared much more quickly following meals, and this reduced pain time was abolished by the use of atropine. In the clinical patient the anginal attacks appear more promptly after ingestion of food. In the experimental animal, distention of the stomach was followed by a decrease in the coronary flow. In each case the effect was abolished by atropine. In the experimental animal the effect did not occur after section of the vagus.

In examining the individual patients by the method described, a fairly wide variation in the response to atropine was observed. It seemed to us that the variation of the pain time in response to atropine was in inverse proportion to the evidence of anatomic cardiac

Chart 4.—The tolerance for 10 per cent oxygen before meals is represented as 100 per cent in the left hand column of each group and is labeled a. c. The tolerance for the gas mixture after atropine, and still before meals, is represented in the right hand column, labeled p. a.

was the fact was shown in table 4. The ingestion of food reduced the tolerance to 10 per cent oxygen of patient 1 by 19 per cent, of patient 2 by 40 per cent. Atropine improved the after meal tolerance for 10 per cent oxygen of patient 1 by 17 per cent, of patient 2 by 87 per cent. The remaining figures in table 4 are those from which the graphs were prepared.

In January of this year, while the work was in progress, Morrison and Swalm¹⁹ published a report in which

Chart 5.—The tolerance for 10 per cent oxygen before a meal is represented as 100 per cent in the left hand column of each group, labeled Cont. (control). The middle column depicts the increased tolerance for the gas twenty minutes after each drug was given. The right hand column represents the tolerance to the gas ten minutes after completion of a meal that was served immediately after the test represented in the middle column.

they approached this problem from a somewhat different angle, and we believe that our results are in every way consistent with theirs.

19. Morrison, L. M., and Swalm, W. A.: Role of the Gastrointestinal Tract in Production of Cardiac Symptoms, J. A. M. A. 114:217-223 (Jan. 20) 1940.

damage. That is to say, the greater the obvious cardiac damage, the less striking is the atropine response. It is probable that the ability of a seriously damaged coronary vessel to dilate or constrict is impaired. We think that this observation indicates a vasoconstriction in the cases in which atropine gave relief. It is quite possible that the character of the atropine response by such patients may be a rough index of the character of the angina. A considerable increase in the tolerance to 10 per cent oxygen as a result of the injection of atropine by patients subjected to this procedure would lead us to suspect that the anginal attack had a large vasoconstrictor element. Conversely, a small atropine response would indicate that the angina was largely due to anatomic changes in the vessel.

CONCLUSIONS

Distention of the dog's stomach under light anesthesia or no anesthesia at all produces coronary vasoconstriction through a vagovagal reflex. This reflex with its resultant coronary constriction may be abolished by atropine or by vagal section.

Anginous patients who were made to breathe 10 per cent oxygen developed anginal pain much more quickly following meals. This reduced pain time was abolished by the use of atropine and, in two of the three patients, atropine caused the after meal pain time to exceed the control pain time.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. LESTER M. MORRISON, Philadelphia: Drs. Gilbert, Fenn and LeRoy have shown the relationship of intragastric gassy distention on the coronary arteries. It is gratifying to find their work in complete agreement with my experimental and clinical studies reported in *THE JOURNAL*, January 20. At that time Dr. Swalm and I recorded the effect and relationship of intragastric and intra-esophageal gassy distention on the coronary arteries and angina pectoris in man for the first time and showed their direct relationship clinically through the vagus arc. When we first conducted our experiments in 1935 it took Dr. Peckham and myself some six months to devise a safe apparatus, because of the danger of inducing a fatal attack in the cardiac cases. Indeed, when I distended the stomach to 100 mm. of mercury pressure one of the patients developed a cardiac standstill and fell unconscious. If we had not constructed our apparatus so that I could relieve the intragastric pressure immediately, I feel certain that the patient would have died then and there. It is a tribute to the skill and ingenuity of Drs. Gilbert, Fenn and LeRoy that their method of approach was so eminently successful. The variability of the time-pain in each of the cases presented indicates the difference in vagal pattern sensitivity in different patients. This calls for saturation dosages of atropine or belladonna for therapeutic effectiveness. Dr. Fenn told me that the experimental meals were given at the lunch hour. Even more striking results may have been obtained following the heavy evening meal, which is a much heavier load placed on the stomach and the vagus nerve mechanism. The clinical inferences of this presentation are significant. In angina pectoris and coronary artery disturbances the necessity is for small, frequent meals, proper diet, antispasmodics, sedatives and xanthine derivatives. The diet should be relatively bland, easily digested and free from all gas-forming foods. Light meals should always be eaten slowly and chewed thoroughly. Active physical exercise or excitement after meals is always hazardous in these cases and is to be avoided at all times. The bowels should function normally and daily. Flatulence is to be avoided like the plague and can be combated with soothing gastric and bowel demulcents, antacid powders, carminatives and absorbents.

DR. CHARLES W. GREENE, Stanford University, Calif.: It is reassuring to find that clinicians are laying more and more emphasis on the part played by physiologic processes in the origin and course of cardiac disorders. The foundation of the nutritive control of the myocardium lies in intimate regulation of the coronary blood flow. It is the details of this regulation that are being uncovered by the numerous coronary researches of the last two decades. Sensory events in every part of the body produce autonomic reflexes directly affecting the rate and volume of the coronary blood flow. It matters not what associated reactions may simultaneously occur. Dr. Gilbert and his colleagues have added the demonstration of the part played by visceral pressure stimulation. A fact not generally known is that the milder and usual functional coronary reflexes take the form of coronary dilatations. Reflex coronary constrictions occur in the normal animal only in response to more vigorous sensory stimulation. If, as is often the case, the constrictor reflex apparatus is hypersensitive or overdeveloped, coronary constrictions are more frequent, even dominant, and may be profound enough to induce varying degrees of myocardial ischemia. The authors have used the two reliable and standard experimental methods applicable to dogs, the coronary sinus method and the electrical stromuhr technic. Each method is difficult but each yields data which supplement the other. The addition of direct experiments on anginal patients is unique. The method arrives at the cardiac crisis sooner. The reported results are positive and definite. Let me emphasize that reflex coronary reactions are almost always associated with cardiac accelerations, not slowing or inhibitions as is too often inferred. This is the explanation of the coronary dilatation as the normal and standard reaction. The coronary dilatation supplies more oxygen when the myocardial consumption is greater. One can appreciate the upset of this physiologic balance when the coronary arteries are reflexly constricted, thus actively reducing the coronary flow. It is equally tragic if the coronaries of the patient are sclerotic or have lost coronary resilience and cannot respond to the associated coronary dilator reflexes when the heart is doing increased work. The authors are to be congratulated for establishing that visceral pressures induce reflex coronary constrictions that hasten anginal attacks.

DR. HEYMAN R. MILLER, New York: These studies touch on two major problems: The first deals with the question Does anoxemia with a resultant myocardial ischemia produce anginal pain? Does anginal pain associated with abdominal distention depend on anoxemia? The other major problem is unrelated to anoxemia and has to do with the transmission of afferent impulses from the abdomen and its viscera to those spinal cord segments at which referred cardiac pain is mediated. Afferent abdominal stimuli are probably also registered in the cardiac apparatus by means of axon reflexes, without passing through the spinal cord. May I ask whether it is not possible to have an anoxemia, a diminished oxygen content in the circulation, and yet an oxygen content in the heart muscle above the critical level requisite for the induction of pain? I put the question because the heart with its special arrangement of autonomic supplies seems able to receive more rather than less blood in the presence of an emergency like asphyxia; the coronary vessels probably dilate. Moreover, in certain experimental and clinical situations the heart, despite low oxygen content of the blood, can remain free of pain. While intense pain will appear at the moment of tightening a ligature around a coronary vessel, shortly thereafter, and despite continued anoxemia of the heart muscle, pain may subside or disappear. Again, at the onset of an acute coronary thrombosis, pain is often intense yet within a few hours cardiac pain may be greatly diminished or absent even though the infarcted segment of myocardium is still deprived of considerable oxygen. These observations are offered not as complete detractors of the general concept that anoxemia may lead to cardiac pain but rather to suggest that factors other than anoxemia alone are at work. The observations of Dr. Greene and his co-workers indicate that a reflex may operate between abdominal viscera and the coronary circulation. I venture to believe, however, that such a reflex may influence coronary flow independent of the mechanism of pain transmission.

THE TREATMENT OF ANURIA DUE
TO SULFAPYRIDINE CALCULI

JOSEPH F. SADUSK JR., M.D.

LEVIN WATERS, M.D.

AND

DWIGHT WILSON, M.D.

NEW HAVEN, CONN.

The symptom complex of hematuria, abdominal pain, and nitrogen retention as a manifestation of sulfapyridine therapy was first described by Southworth and Cooke,¹ although the occurrence of hematuria had been previously noted.²

Animal experiments by Antopol and Robinson,³ Gross, Cooper and Lewis⁴ and Toomey⁵ early revealed the pathologic changes in the urinary tract of rats, rabbits and monkeys receiving sulfapyridine. Since then, Antopol and Robinson⁶ and Toomey, Reichle and Takacs⁷ have studied these changes in great detail. Briefly they are as follows: in the kidneys, striking dilatation of the glomerular spaces and tubules; thickening of the basement membranes of the glomerular tufts with changes in the shape of the cells of the capsular epithelium; in the collecting tubules, debris and spaces, apparently the lodging place of crystals of the precipitated drug; in the pelvis and ureters, concretions, with denuding of the epithelium, clotted blood, mucosal hemorrhages and marked edema.

The seriousness of this manifestation of sulfapyridine treatment in man became evident with the report of a death from total anuria by Tsao and his co-workers.⁸ This report was of particular interest in that the finding of complete ureteral obstruction due to concretions blocking both ureterovesical orifices was described. These authors suggested the use of cystoscopic treatment, believing that their patient would have survived if this procedure had been carried out.

Recently Carroll, Shea and Pike⁹ have successfully treated by cystoscopy a patient who had complete anuria due to sulfapyridine calculi and have recorded the finding of ureteral obstruction by calculi at the ureterovesical orifices.

Our purpose in the present contribution is to offer additional evidence (1) that complete anuria due to

sulfapyridine may be caused by ureteral obstruction and (2) that this condition can be treated effectively by means of cystoscopy. The renal pathologic changes in one instance of acute sulfapyridine anuria will be described.

REPORT OF CASES

CASE 1.—History.—A man aged 35, Italian, a laborer, was admitted on Feb. 3, 1940, to the Neurosurgical Service of the New Haven Hospital following a traumatic injury to the head with penetration of a foreign body into the right frontal region of the brain. Little was known of his past history other than that he had enjoyed good health up to the time of the accident.

On admission the patient was unconscious, breathed stertorously and did not respond to stimuli. The temperature was 100.2 F., pulse 88 and respiratory rate 48. The blood pressure was 190 systolic, 120 diastolic but shortly after admission fell to 110 systolic, 80 diastolic. Examination revealed a deep laceration of the right frontal region in which was embedded a foreign object. Shortly after admission the patient

Fig. 1 (case 1).—Retrograde pyelogram before lavage of kidney pelvis.

fell into shock but after operative removal of the foreign body and blood transfusion he rallied and his condition seemed quite satisfactory.

Following operation the administration of sulfapyridine was commenced as a prophylactic measure but, despite this, infection of the operative wound set in within forty-eight hours and cultures of the pus yielded a growth of hemolytic *Staphylococcus albus* and *aureus*. Essential details of the patient's course are outlined in table 1. On the first day he received 3 Gm. of sulfapyridine, the first 2 Gm. of which was administered subcutaneously in 750 cc. of saline solution and 750 cc. of 5 per cent dextrose. All subsequent sulfapyridine was given by mouth in the amount of 1 Gm. every four hours until February 6. On this date because of a rather low blood level of free sulfapyridine the dosage was increased to 1 Gm. every three hours.

At noon on February 7 the patient complained of pain in the flanks. That night the urine was found to be of a dark amber color and to contain about 25 red cells per high power field in an uncentrifuged specimen. Sulfapyridine was immediately discontinued and fluids were forced as much as possible under the circumstances of the accompanying neurologic condition.

The following day the patient was irritable but responded well to stimuli. Respirations were rapid. The left retinal fundus was normal in appearance. The lungs were clear throughout, and examination of the cardiovascular system revealed no abnormalities. The abdomen was greatly distended and tym-

Fig. 2 (case 1).—Retrograde pyelogram after lavage of kidney pelves.

panic. Palpation over both costovertebral angles showed definite tenderness. There was no peripheral edema. Little fluid had been taken by mouth. Consequently fluids were given parenterally in a total amount of 3,100 cc. as follows: 300 cc. transfusion of blood, 1,000 cc. of 10 per cent dextrose solution and 300 cc. of physiologic solution of sodium chloride intra-

Fig. 3 (case 1).—Section of renal cortex showing dilatation of tubules and glomerular spaces. Reduced from a photomicrograph with a magnification of 100 diameters.

venously, and 1,000 cc. of physiologic solution of sodium chloride and 500 cc. of 5 per cent dextrose solution by hypodermoclysis.

During the remainder of the day the patient complained rather bitterly of persistent pain in the flanks and difficulty in voiding. At 4:30 p. m. he passed 60 cc. of grossly bloody urine, his last voided specimen.

Following this there was complete anuria during the next twenty-four hours, despite intravenous injection of physiologic solution of sodium chloride and 50 per cent dextrose. The possibility of sulfapyridine calculi blocking the ureters was considered and it was decided that cystoscopy was indicated, since the patient's nonprotein nitrogen was now 76 mg. per hundred cubic centimeters.

A No. 24 French cystoscope was passed with ease. Approximately 50 cc. of pinkish cloudy amber urine was found in the bladder and showed the characteristics detailed in table 2. In it were many long slender crystals and large flat ones which were jagged and irregular. The bladder capacity was less than 100 cc. The mucous membrane was injected and a few small blood clots were present. The ureteral orifices were inflamed and a small blood clot was seen protruding from the left meatus. Neither ureteral orifice passed any urine. Attempts to pass the ureteral catheters met obstruction on both sides at a depth of 1 cm. The catheters were then withdrawn and after the passage of No. 5 filiform tipped bougies, No. 7 French ureteral bougies were passed to the renal pelvis on both sides. Following withdrawal of these, a sharp, multipointed concretion was seen extruding from the right ureteral orifice. This was easily dislodged. Each ureteral orifice was now seen to produce bloody urine and on catheterization yielded urine as described in table 2.

Fig. 4 (case 1).—Section of renal pelvis showing the loss of epithelium and the massive hemorrhagic infiltration of the lamina propria mucosae. Note also the congestion of the submucosal vessels and the cellular infiltration of this layer. Reduced from a photomicrograph with magnification of 40 diameters.

An x-ray film of the abdomen was rather unsatisfactory because of intestinal distention, but no evidence of radiopaque renal or ureteral calculi was found. A retrograde pyelogram (fig. 1) revealed poorly outlined renal pelves with mottling and hazy outlines. Both catheters were now repeatedly washed out with warm sterile water for a period of about thirty-five minutes. At the end of this period the urine draining from the left catheter was fairly clear while that draining from the right catheter remained blood tinged. A retrograde pyelogram (fig. 2) now revealed more sharply outlined kidney pelves. The ureteral catheters were allowed to remain in place, the left producing from 50 to 60 drops a minute and the right from 30 to 40 drops a minute.

The patient was then returned to the ward and during the next two hours continued to excrete urine satisfactorily from both catheters, at the end of which time he pulled the catheters out of place. Shortly after this, 1,000 cc. of 5 per cent dextrose solution was given slowly by the intravenous route. Approximately thirty minutes after the infusion was finished the patient lapsed into coma and, despite supportive measures, died of respiratory failure, presumably due to cerebral edema and medullary compression.

Pathologic Examination.—Autopsy was limited to an examination of the kidneys and the upper portions of the ureters. Grossly the kidneys were enlarged, the right weighing 230 Gm. and the left 215 Gm. The measurements for the right were 12 by 7 by 5 cm. and for the left 12 by 6 by 4.5 cm. Both

Fig. 5 (case 2).—Retrograde pyelogram before lavage of kidney pelvises.

organs were light brown and quite soft. Their capsules stripped with ease, leaving a smooth surface on which there was no evidence of potential hemorrhages. On longitudinal section the

Fig. 6 (case 2).—Retrograde pyelogram after lavage of kidney pelvises.

cut edge of the renal tissue bulged slightly, denoting increased tension. The cortical and medullary markings of the parenchyma were distinct, the cortex measuring from 6 to 8 mm. in diameter. No gross hemorrhages could be identified on the cut surface. There was no dilatation of the renal pelvises or ureters but the mucosal surfaces of these structures were markedly altered

in appearance. Much red-brown clotted blood, rather granular in consistency, filled the calices and was adherent to large areas of the pelvic and ureteral mucosa. Where there was no actual clot the pelvis and ureteral mucosal surfaces were hemorrhagic, being raised here and there into small bleblike masses filled with blood. The walls of the pelvises and ureters were markedly edematous. No concretions were present, but in the calices, mixed with the clotted blood, were found small amorphous masses of a light red-brown material which was gritty to palpation. Under the microscope numerous needle shaped and sheaflike crystals were identified. Chemical analysis¹⁰ of this material revealed the presence of 45 per cent acetylated sulfapyridine and 6 per cent free sulfapyridine.

Microscopically the most striking change in the kidney proper was the great dilatation of the convoluted and collecting tubules and of the glomerular spaces. A considerable amount of eosinophilic granular material was observed in the convoluted tubules. In a few of the collecting tubules, basophilic amorphous masses were found but no other concretions or crystals were present. The glomerular changes were interesting. In addition to the distention of Bowman's capsule the tufts were enlarged with greatly congested capillaries and a much vacuolated intercapillary basement membrane. In numerous tufts the red blood cells within the capillaries were apparently fused or conglu-

Fig. 7 (case 2).—Sheaf of crystals of acetyl sulfapyridine recovered from the ureteral calculi; $\times 200$.

minated to form homogenous eosinophilic masses. Neither necroses of the glomerular tufts nor intracapsular hemorrhages were found. The epithelium of the renal tubules was intact throughout. Focal areas of capillary congestion were frequent and there was much interstitial edema.

The renal pelvises showed for the most part absence or necrosis of their transitional epithelium. The lamina propria mucosae was edematous and contained large hemorrhagic extravasations, some of which resulted in the nodular masses noted grossly. Numerous lymphocytes and polymorphonuclear leukocytes were present. Similar hemorrhagic extravasations and cellular accumulations extended in focal zones through the submucosa well up into the medullary renal tissue.

Microscopically the ureters showed extensive mucosal hemorrhages, great edema of all the coats of the wall and an abundant lymphocytic and polymorphonuclear cellular infiltration.

CASE 2.—A man aged 39, Italian, a laborer, was first admitted for therapy to the Medical Service of the New Haven Hospital on Dec. 11, 1939, with a subacute gonorrheal urethritis, prostatitis and arthritis. Some degree of improvement occurred on sulfanilamide therapy, but the patient left the hospital against advice on Dec. 26, 1939.

10. Chemical analyses in this report were performed by Miss Anne Seymour.

Eight days after discharge the patient again had a urethral discharge, which was shortly followed by pain and swelling of both ankles and the right knee. He was readmitted on Feb. 7, 1940, with an arthritis of both ankles and the right knee, the latter being quickly followed by spread to the left knee. His temperature was 102 F. and blood pressure 120 systolic, 80 diastolic. The leukocyte count was 11,300. Examination of the urine revealed no albumin or red cells, but from 1 to 2 leukocytes per high power field were present. X-ray examination of the ankles and right knee revealed changes consistent with a subacute infectious arthritis.

After a preliminary period of observation, sulfathiazole therapy was begun, the patient receiving an initial dose of 4 Gm. followed by 1 Gm. every four hours. No response in temperature or symptoms was obtained and after six days of therapy sulfathiazole was discontinued. Specific details as to the laboratory data are contained in table 4.

Twenty-four hours after the discontinuance of sulfathiazole the blood concentration of the drug had fallen to a trace, and eight hours after this determination sulfapyridine therapy was begun, the patient receiving an initial dose of 4 Gm. and then 1 Gm. every four hours. On the third day of sulfapyridine therapy (February 19) it was noted that 55 per cent of the drug in the blood was acetylated, but in view of a normal urine, a nonprotein nitrogen of 27 and a satisfactory urine output it seemed advisable to continue sulfapyridine therapy. Late that night the patient complained of lower abdominal pain but nothing was found on physical examination except abdominal distention.

Intake and output levels on twenty-four hour specimen from 7 a. m. to 7 a. m. The fluid intake includes fluids given parenterally.

At 4 o'clock the following morning (February 20) the patient passed a dark smoky urine containing innumerable red cells, 3 plus albumin and numerous crystals, among which were a type resembling bound sheaves of wheat. This specimen contained 92.4 mg. per hundred cubic centimeters of free sulfapyridine and 235 mg. total sulfapyridine (61 per cent acetylated). From this point on the patient had an essentially complete anuria and now complained of rather severe pain definitely localized over the suprapubic area and the costovertebral angles. The nonprotein nitrogen had risen to 35 mg. per hundred cubic centimeters and total blood sulfapyridine to 13.7 mg., 57 per cent of which was acetylated. There was a leukocytosis of 22,200, 85 per cent of the cells being of the granulocytic series.

Sulfapyridine was immediately discontinued and fluid forced both orally and parenterally, the patient receiving 1,000 cc. of 10 per cent dextrose intravenously and 3,250 cc. of physiologic solution of sodium chloride and 750 cc. of 5 per cent dextrose by hypodermoclysis. During the course of the day the patient complained bitterly of pain in the flanks and lower part of the abdomen. There was costovertebral tenderness, more marked on the right.

Except for 5 cc. of bloody urine passed at 5 a. m. February 21, which had essentially the same characteristics as the last specimen passed on February 20, no further urine was produced. By the morning of February 21 he had become drowsy and lethargic. The nonprotein nitrogen had risen to 45 mg. per hundred cubic centimeters and the total blood sulfapyridine to 15 mg., 67 per cent of which was in the acetylated form. At 3:30 that afternoon, after anuria for thirty-six hours, cystoscopy was performed.

A No. 24 French cystoscope was passed without difficulty, a slightly grating sensation being noted. About 20 cc. of grossly

bloody urine was found in the bladder. The bladder capacity was 200 cc. The bladder mucous membrane was fairly normal except for moderate inflammation in the region of the trigon. There were numerous mucous shreds and yellowish concretions in the base of the bladder. Neither ureteral orifice produced

any urine. The right ureteral orifice was swollen, edematous and dusky red, and humped up on a mount about 1 cm. in diameter. Protruding from the ureteral orifice could be seen a large irregular concretion completely filling the meatus. The left ureteral orifice was similarly involved but less edematous and was also completely filled with a calculus. No. 5 French ureteral catheters were then passed. There was moderate obstruction for a distance of about 2 cm. from the meatus. Beyond this point they passed without difficulty to the renal pelves, urine dropping from the left ureteral catheter quite steadily, but more slowly on the right. The right ureteral catheter was then withdrawn momentarily and a most remarkable sight was seen. Pouring from the right ureteral orifice was a thick sludge, probably sulfapyridine "sand," quite similar in appearance to the pouring of a thick semisolid cement mixture. After this material was discharged the catheter was reinserted and ureteral specimens were taken for examinations which are summarized in table 3. An x-ray film of the abdomen revealed no radiopaque calculi present. A retrograde pyelogram (fig. 5) revealed a dilatation of the right ureter. The renal pelves were fairly normal though rather mottled in appearance,

this being especially true of the right kidney pelvis. The catheters were then thoroughly lavaged with warm distilled water and the pyelogram was repeated (fig. 6), showing better filled pelves with clearer outlines.

Phenolsulfonphthalein was injected intravenously, appearance times of the drug being four and one-half and three minutes respectively on the left and right sides. Excretion on the left side in fifteen minutes was 2.5 per cent, while on the right side

it was approximately 10 per cent, the latter figure being unreliable owing to the presence of blood. A number of small stones were then washed out of the bladder and preserved. They were yellowish white, irregularly spherical and easily crushed. Microscopically they were made up for the most part of groups of crystals resembling bound sheaves of wheat (fig. 7) together with a number of long slender needles (probably from the breaking up of the sheaves) and crystals of nonacetylated sulfapyridine. Chemical analysis of these calculi showed that they contained 55 per cent of acetylated sulfapyridine and 7 per cent of free sulfapyridine.

The ureteral catheters were allowed to remain in place for the next twelve hours. Urine dropped steadily from each ureteral catheter, and from time to time the patient voided spontaneously around the catheters. During this period the left catheter yielded 255 cc. of urine containing 35 mg. per hundred cubic centimeters of free sulfapyridine and 110 mg. of total sulfapyridine (68 per cent acetylation), the right catheter 370 cc. of urine containing 37.5 mg. per hundred cubic centimeters of free sulfapyridine and 115 mg. of total sulfapyridine (67 per cent acetylation).

Following removal of the catheters the patient continued to pass considerable quantities of a dark smoky urine containing

McLellan.¹¹ Under these circumstances treatment of sulfapyridine hematuria by means of forced fluids alone seems ample, since data¹² have been offered to suggest that the concretions may be redissolved or washed out.

If, however, complete anuria is present or if the possibility of a unilateral obstruction is evident, cystoscopy should be done without delay to determine whether or not urine is being passed from the ureteral orifices. If not, catheterization of the ureter, a filiform tipped bougie being used if necessary, should be carried out and the kidney pelvis and ureter thoroughly lavaged with warm distilled water until the urine drips from the catheter and retrograde pyelograms reveal a clearly outlined upper urinary tract.

It is perhaps preferable to leave the ureteral catheters in place for the next twelve hours, though this may not be absolutely necessary. From time to time the catheters should be irrigated with warm saline solution and after their withdrawal fluids should be continually

red cells, albumin, mucous shreds and many very small calculi, which on microscopic examination showed again the presence of large jagged crystals, apparently broken up acetylated sulfapyridine crystals. He continued to pass similar urine until the night of February 22, following which the urine assumed a slightly cloudy, yellow appearance. The urine continued to clear, the albumin disappeared and only rare red and white cells were found. At the time of discharge the urine was entirely negative save for an occasional leukocyte. Casts were never found in the urine at any time. Phenolsulfonphthalein excretion on February 26 was 63 per cent in two hours. An intravenous pyelogram revealed normal kidney pelvis and normal ureters, the dilatation of the right ureter previously observed being no longer present.

The patient was discharged on March 12, 1940, in good condition with temperature normal, arthritis practically subsided and normal urinary status.

COMMENT

In both cases there remains no doubt that the anuria was due to concretions blocking the ureterovesical orifices, thus confirming the observations of Tsao and his co-workers⁸ and Carroll, Shea and Pike.⁹

That concretions may exist without blocking the ureters has been demonstrated by Plummer and

forced with close observation of the urinary output for the next forty-eight hours.

The conditions under which sulfapyridine hematuria and concretions develop are still not clear. Acidity of the urine has frequently been suggested as a factor and the simultaneous administration of sodium bicarbonate with the sulfapyridine to alkalize the urine has been advised. That this procedure is of little value has been demonstrated by clinical⁸ and experimental⁷ observations. In addition there has been observed in this hospital an instance of sulfapyridine hematuria developing in a patient receiving adequate amounts of sodium bicarbonate, whose urine was alkaline at the time of hematuria. Haviland and Bratton¹³ have shown that the solubility of acetyl sulfapyridine in urine remains essentially the same for a range of p_H 3.3-7.4, and that the solubility at p_H 7.9 is not enough to be of therapeutic advantage.

12. Antopol and Robinson.⁸ Plummer and McLellan.¹¹

13. Personal communication to the authors from Dr. James W. Haviland and Dr. A. Calvin Bratton, Johns Hopkins University, Baltimore.

Another factor suggested and one which has seemed most likely, has been that of a low urinary output. The validity of this explanation, however, must be seriously challenged in the light of recent experience. In case 2 the urinary output would appear to have been quite adequate and, furthermore, instances have been observed in this clinic in which the urinary output has been far less without the development of hematuria or other associated symptoms. Moreover, Toomey, Reichle and Takacs⁷ have demonstrated that the administration of large quantities of fluid to the *Macaca mulatta* monkey has not prevented either the formation of stones or the development of pathologic changes in the urinary tract.

It is of interest that, in the cases presented in this report, acetylation of sulfapyridine both in the blood and in the urine was abnormally high. This has been true, in general, of the cases of sulfapyridine hematuria observed in this hospital,¹⁴ but it must be pointed out again that similar degrees of acetylation have been observed in cases which have not exhibited any sign of urinary abnormality.

Toomey and his co-workers⁷ have made the interesting observation that the sodium salt of sulfapyridine, when used in comparable doses, is more apt to produce toxic urinary symptoms than is sulfapyridine. The significance of this observation is not exactly clear at the present time.

In general, the pathologic changes in case 1 were entirely in accord with those found experimentally in monkeys by Antopol and Robinson.⁶ They consisted essentially of great tubular and capsular dilatation, marked congestion and vacuolization within the glomerular tufts, and an acute hemorrhagic pyelo-ureteritis extending into the adjacent renal medullary tissue. A similar pathologic description in man has been given by Tsao and his associates,⁸ and Plummer and McLellan¹¹ mention petechial hemorrhages in the pelvis of the kidney.

On the other hand, while Stryker¹⁵ found dilatation of the tubules and capsular spaces in the kidneys of a patient, he observed no changes in the mucosal surfaces of the urinary tract. He believes that certain basophilic masses found plugging the tubules are responsible for the tubular dilatation and represent crystals of precipitated drug. A few such masses were found in the collecting tubules of the kidneys described in the present case. Since the tissues were fixed in Zenker-acetic or in solution of formaldehyde and even washed during the staining process, it is possible that many more of these bodies were originally present. However, Strong¹⁶ has shown in recent animal experiments that some tubular and capsular dilatation can occur acutely from ureteral obstruction alone, so that this factor must be considered also in explaining the kidney changes in the case described in the present report.

SUMMARY

1. Two cases of complete anuria occurring during sulfapyridine therapy were observed.
2. In both cases anuria was due to calculi blocking the urinary tract at the ureterovesical orifices.
3. Treatment by means of cystoscopy was successful.

4. The pathologic changes in the upper urinary tract of a patient dying of a neurosurgical complication consisted essentially of great tubular and capsular dilatation, marked congestion and vacuolization within the glomerular tufts, and an acute hemorrhagic pyelo-ureteritis extending into the adjacent renal medullary tissue.

PERIPHERAL NEUROPATHY DUE TO VITAMIN B₁ DEFICIENCY IN DIABETES MELLITUS

HARRY D. FEIN, M.D.

ELAINE P. RALLI, M.D.

AND

NORMAN JOLLIFFE, M.D.

NEW YORK

We are reporting nine cases of a symmetrical peripheral neuropathy due to vitamin B₁ deficiency found in a group of 422 ambulatory patients with diabetes mellitus. The occurrence of peripheral neuropathy in diabetic patients is well known and has been the subject of several reports since its description by Marchal de Calvi¹ in 1864. The incidence of this condition in groups of such patients varies, according to Jordan,² from 0.6 to 57.3 per cent. The extreme variation thus reported demands explanation and is due, in our opinion, to several factors. There is, first, a tendency on the part of many physicians to label vague pains in the extremities as neuritis without employing objective criteria for the diagnosis of peripheral neuropathy. Pain in the extremities of diabetic patients is common; it occurs in 17 per cent of Joslin's³ patients. Such pain, however, is more often due to arterial and venous circulatory disturbances, arthritis, myositis or mechanical and fatigue phenomena than to peripheral neuropathy resulting from vitamin B₁ deficiency. Another factor is the failure to perform an adequate neurologic examination, especially in the absence of a history of pain in the extremities. Pain, though nearly always present at some time during the course of peripheral neuropathy, may be absent by the time the patient is examined, and its history can be elicited only by leading questions.

That vitamin deficiency may be an etiologic factor in the peripheral neuropathy of diabetic patients was first pointed out by Wohl⁴ in 1926 on the basis of the dietary history, clinical observations and results of treatment with yeast and yeast concentrates of a patient with diabetes. Then in 1928 Angle⁵ noted improvement in a case of "diabetic tabes" following a diet rich in vitamins. The following year Minot⁶ encountered two diabetic patients with peripheral neuritis who improved slowly by taking large amounts of yeast concentrate. The work of Wechsler⁷ and of Root and Rogers⁸

further suggested that these patients have, as a rule, an inadequate intake of food and vitamins and that their clinical and neuropathologic manifestations and response to treatment were similar to those of patients having beriberi.

Since then Vorhaus and his co-workers,⁹ in 1935 and Sciclounoff and Broccard¹⁰ in 1936, as a result of therapeutic application of thiamine hydrochloride, have stated that a deficiency of vitamin B₁ was the etiologic factor in the neuritis of diabetes. Unfortunately, neither of these groups described their criteria for the diagnosis of peripheral neuropathy or detailed the objective observations before and after treatment, although they mentioned in general pains, paresthesias, tenderness and altered reflexes.

On the other hand, Needles,¹¹ on the basis of careful dietary analysis, reported three cases of diabetes presenting definite peripheral neuropathy in which the diets were apparently adequate as judged by the vitamin

of peripheral neuropathy. A total of 422 patients were so examined. To avoid the diagnostic problem already discussed we have followed the criteria of one of us¹² for the diagnosis of peripheral neuropathy due to vitamin B₁ deficiency. These criteria require the presence of a definite bilateral symmetrical polyneuropathy involving first and predominantly the lower extremities. The minimum observations necessary to establish this diagnosis consist in sensory changes in a peripheral nerve distribution in the lower extremities (such as plantar hyperesthesia, which may extend up the ankles and legs in a sock distribution, tenderness of calf muscles and loss of position sense and of vibratory sensation, beginning first in the toes and later extending proximally) plus at least absence of ankle jerks. Peripheral neuropathy of this extent, limited to the lower extremities and with the knee jerks preserved, is designated as mild. If, in addition, the knee jerks are lost, the neuropathy is classified as moderate; if

TABLE 1.—Clinical Data

B₁/calory ratio. A sample diet for a single day was utilized in these estimations. One of his patients freely admitted dietary infractions which would significantly lower this ratio. Substitution of food low in vitamin B₁ but containing equivalent carbohydrate and caloric values is frequent in all groups of diabetic patients and may explain how a prescribed adequate diet becomes actually inadequate in vitamin B₁.

The object of this study was to determine the incidence of definite peripheral neuropathy due to vitamin B₁ deficiency in a large group of diabetic patients and the response to specific therapy.

MATERIALS AND METHOD OF STUDY

The subjects in this study were all ambulant patients who attended the diabetic clinic of the Third (New York University) Division of Bellevue Hospital during 1939. Each patient was subjected to a neurologic examination specifically aimed at discovering evidence

there is involvement of the upper extremities, the spinal cord or the cranial nerves, or if a "central neuritis" is present, it is classified as severe. Peripheral neuropathy that involves a single nerve, that is not bilateral and symmetrical, or does not involve first and predominantly the lower extremities (in ambulatory patients) is excluded as probably not due to vitamin B₁ deficiency alone. For such neuritides other etiologic agents should be sought. These, such as lead, arsenic, triorthocresol phosphate and bacterial and virus infections, may and do operate in the diabetic as well as in the nondiabetic person, and the type of peripheral neuropathy they produce seldom fulfils the criteria for the diagnosis of neuropathy due to B₁ deficiency.

All patients in whom the objective criteria necessary for the diagnosis of mild peripheral neuropathy were found were designated as suitable for a therapeutic test. Those having only suggestive signs were excluded. The designated patients, without otherwise changing their diet, were given 10 mg. of synthetic thiamine hydrochloride by mouth daily throughout the period of observation; follow-up observations were performed

weekly for a period of at least six months. All conditions remained constant except the adjustment of insulin as required.

RESULTS

Of a total of 422 patients, nine, or 2.1 per cent, fulfilled the criteria for the diagnosis of peripheral neuropathy resulting from vitamin B₁ deficiency. In these nine subjects there were no abnormal neurologic manifestations other than the peripheral neuropathy, and no other clinically evident vitamin deficiencies. In table 1 are presented the clinical data, such as age, sex, duration of diabetes, diet, use of insulin, status of diabetic control and complications. None of these patients had evidence of ketosis during the period of study. There were four men and five women, the ratio of males to females in the entire group of 422 subjects being approximately the same. All nine subjects were 50 years of age or over, while 69 per cent of the whole group of 422 patients were over 49 years of age. The known duration of the diabetes of the nine patients varied from six months to thirty years, with an average of 6.7 years. The average duration of diabetes in the 422 patients was 8.3 years.

The neurologic observations and the results of therapy are summarized in table 2. Tenderness of the calf muscles, plantar hyperesthesia and loss of ankle jerks were present in all nine subjects; some degree of loss of vibratory sensation was found in three, while the position sense was intact in all. No subject showed more than mild peripheral neuropathy according to our criteria. After therapy, plantar hyperesthesia disappeared in all cases after four weeks and in three after two weeks. Tenderness of the calves disappeared in all cases after six weeks and in five cases after two weeks. Vibratory sensation in the toes was absent in three subjects, returning to normal after eight and ten weeks respectively in two subjects but remaining absent in the toes of one subject (case 3) after six months of treatment. The ankle jerks returned after two weeks in one subject and within fourteen weeks in eight subjects; in one subject (case 3) they had not returned at the end of six months.

Some patients not tabulated in this study complained of persistent unilateral pain in an extremity, while others experienced vague aches and pain in the extremities. Neurologic examination of these patients disclosed no objective signs of bilateral symmetrical peripheral neuropathy. These subjects were treated with thiamine hydrochloride, vegex or brewers' yeast. The results were not uniform. In some the relief was apparently sustained; in others it was temporary, while in still others no relief was experienced.

COMMENT

We believe that the symmetrical peripheral neuropathy found in these nine diabetic patients was due to vitamin B₁ deficiency. This belief is based on the following reasons: First, the clinical characteristics fulfilled the established criteria for the diagnosis of peripheral neuropathy due to vitamin B₁ deficiency; second, without otherwise changing the diet or therapy, the addition of 10 mg. of synthetic thiamine hydrochloride daily by mouth was followed by cure in eight cases and by objective improvement in the ninth.

The explanation of the development of peripheral neuropathy due to vitamin B₁ deficiency in these nine subjects is speculative, but in our opinion it is due

directly to eating a diet of borderline adequacy in vitamin B₁. On the basis of Cowgill's¹³ prediction formula, the diets prescribed for these patients were all adequate in that the vitamin B₁/calory ratio ranged from 3.2 to 4.3, representing an excess of 140 to 210 per cent over their predicted minimal requirements. One of us¹⁴ has recently suggested that diets representing a vitamin B₁/calory ratio of 2.3 or more are definitely adequate, those less than 1.7 are definitely inadequate, and those between 1.7 and 2.3 are of borderline adequacy. By this criterion all the prescribed diets were above the borderline range, furnishing safety margins of from 39 to 87 per cent. As we had previously pointed out, however, substitution of foods poor in vitamin B₁ (such as white bread or crackers) but con-

taining equivalent carbohydrate and caloric values for prescribed foods richer in vitamin B₁ is common in all groups of diabetic patients. This was especially true in our patients because of their poor economic condition. In view of this it is surprising that a peripheral symmetrical polyneuropathy developed in but 2.1 per cent of the patients. There are, moreover, several other possible contributory factors. The most important of these, we believe, may be arteriosclerosis. This is suggested by the age distribution of our patients. Woltman and Wilder,¹⁵ in a study of the peripheral nerves of ten diabetic patients, observed arteriosclerosis of the small arteries in the nerve tunnels of the legs of all subjects and areas of degeneration in the nerves of nine subjects. This vascular inadequacy may require a

higher concentration of thiamine in the blood, to provide sufficient vitamin to the nerves, than in subjects with normal arteries, as pointed out by Naide.¹⁶ Another factor may be the polyuria¹⁷ accompanying glycosuria, which, if persistent, may cause an increased excretion of vitamin B₁ in the urine, rendering it less available for use by the body. This factor may have played a role in six of our nine subjects who, because of lack of cooperation, either voluntary or due to economic circumstances, showed persistent though moderate glycosuria without ketosis. Another factor, of doubtful importance, may be the presence of a disturbance in carbohydrate metabolism in diabetic persons which might conceivably interfere with the utilization of thiamine hydrochloride. Too little is known concerning this relationship to deny its influence, but two facts are available that cast doubt on its significance. The first is that peripheral neuropathy in our subjects occurred in the older age group with relatively mild diabetes, rather than in the younger group with the more severe diabetes. The second fact is that thiamine hydrochloride administered by mouth caused prompt improvement, showing that these diabetic patients could utilize from this amount of the vitamin given by mouth enough to cure or improve the clinical manifestations of the deficiency. Another factor, which does not seem to apply to any of our patients but which under certain conditions may be contributory, is the institution of insulin therapy and the resulting increased utilization of carbohydrate. In subjects whose stores and intakes of vitamin B₁ are of borderline adequacy, the increased utilization of carbohydrate will require additional vitamin B₁. Unless precautions are instituted, polyneuropathy may result from vitamin B₁ deficiency. Hausman¹⁷ has recently observed three such cases. In this connection it is interesting to note that Sydenstricker, Geeslin and Weaver¹⁸ observed the development of clinical signs of pellagra in two diabetic patients when the carbohydrate content of the diet was increased and added insulin was administered to insure utilization of the augmented diet. They concluded that, "under chronic conditions, signs of avitaminosis might be expected to appear, with or without ketosis, when unusually rapid dextrose metabolism is brought about by the use of insulin."

SUMMARY

We have studied 422 ambulant diabetic patients. Nine (2.1 per cent) had a symmetrical peripheral neuropathy characteristic of the peripheral neuropathy found in subjects having proved vitamin B₁ deficiency. Treatment by daily administration of 10 mg. of thiamine hydrochloride by mouth, without otherwise changing the regimen, resulted in cure of eight subjects and improvements in the ninth.

Indifferent or inconsistent results were obtained on treating neuropathy of single nerves or the vague aches and pains of the diabetic patient.

CONCLUSIONS

The symmetrical peripheral neuropathy beginning first in, and involving primarily, the lower extremities of patients having diabetes mellitus responds to thiamine hydrochloride and in our opinion is due to vitamin B₁ deficiency.

THE COEXISTENCE OF BRUCELLA INFECTION AND HODGKIN'S DISEASE

A CLINICAL, BACTERIOLOGIC AND IMMUNOLOGIC STUDY

N. BOWMAN WISE, M.D.

AND

MARY A. POSTON, M.A.

DURHAM, N. C.

The isolation of *Brucella melitensis* from cultures of lymph nodes from patients having Hodgkin's disease opened an interesting field of investigation.¹ Subsequently fourteen consecutive cases of Hodgkin's disease have been studied carefully for evidence of *Brucella* infection. The clinical, bacteriologic and immunologic observations in seven cases in this series are presented in detail and in the remainder are summarized briefly.

Cultures have been taken of a part of every excised lymph node² and the remaining part has been prepared for pathologic study. In every case the clinical diagnosis of Hodgkin's disease has been confirmed by histologic section of the lymph nodes, taken for biopsy, and the existence of *Brucella* infection has been demonstrated by the isolation of the organisms from either the blood or the lymph nodes or both. The agglutinin-absorption tests and the bacteriostatic reactions of dyes have been used to determine the species of *Brucella*. The technics used for the agglutination reaction and for the determination of the opsonocytaphagic index have been previously reported.³ Because the *Brucella* organisms isolated from patients with Hodgkin's disease have been found to differ significantly from the usual laboratory strains,⁴ agglutination reactions and opsonocytaphagic index determinations have recently been carried out both with the usual laboratory *Brucella* strain and with an encapsulated strain isolated from a patient having Hodgkin's disease. The opsonocytaphagic index number has been calculated by the method of Foshay and Le Blanc.⁵

The cases are reported here in the sequence in which they came under observation.

REPORT OF CASES

CASE I.—R. P., a white man aged 24, who entered the hospital on Oct. 26, 1938, had become ill in November 1937 with enlargement of the right cervical lymph nodes and he was treated by excision and superficial radium therapy. At the time of entry a lymph node from 3 to 4 cm. in diameter and several smaller nodes were palpable in the right cervical region. *Brucella melitensis* var. *suis* was isolated from a right cervical lymph node which had the characteristic histopathologic appearance of Hodgkin's disease. The enlarged lymph nodes regressed under treatment with sulfanilamide and serum from a person considered immune to *Brucella* infection. The patient was discharged from the hospital Dec. 27, 1937, and was followed at close intervals. There was no evidence of activity

of the Hodgkin's disease process until January 1940, when the right cervical lymph nodes again enlarged. Repeated cultures taken of the blood and lymph nodes have been negative.

It is considered that further observation is necessary to determine the true significance of the isolation of *Brucella* from this patient.

CASE 2.—*Enlargement of cervical, axillary, inguinal and mediastinal lymph nodes of ten months' duration; culture of a cervical node yielded Brucella melitensis var. melitensis; regression of enlargement of lymph nodes under sulfapyridine therapy; recurrent enlargement of inguinal and femoral lymph nodes on the left; Brucella melitensis var. melitensis isolated from blood cultures; treatment with sulfapyridine and immune serum; temporary improvement.*

M. W., a Negro boy aged 5 years, who was brought to the hospital Nov. 16, 1938, had enlargement of the neck of ten months' duration. In February 1938 a firm, painless swelling appeared below the angle of the left jaw which alternately subsided and recurred. For a week preceding the hospital visit the patient had had a mild cold with nonproductive cough, and a tender swelling had appeared in the left groin.

On physical examination the temperature was 37 C. (98.6 F.), the pulse rate 120 and the respiratory rate 20. The child was well nourished and did not appear ill. There was a firm, nontender mass of lymph nodes measuring 6 by 8 cm. in the left cervical region. The right cervical nodes were enlarged to a lesser degree. The left axillary nodes were markedly enlarged, one node measuring 4 cm. in diameter. The right axillary and inguinal nodes were enlarged. Retromanubrial dullness measured 5 cm. The heart and lungs were not remarkable. There was no abdominal tenderness and no organs were palpable. On rectal examination a firm, nontender mass was felt on the left side.

Wassermann and Kahn reactions of the blood were negative; examination of the blood showed hemoglobin 62 per cent, white blood cells 16,700, with polymorphonuclear leukocytes 80 per cent (stab cells 12 per cent), eosinophils 0, basophils 0, large lymphocytes 3 per cent, small lymphocytes 17 per cent and monocytes 0; *Brucella* agglutination was negative; an intracutaneous tuberculin test (1:1,000) gave negative results.

Permission for the biopsy of a lymph node was refused and the patient was not seen again until December 7. His condition had remained unchanged until the preceding five days, when loss of appetite and an evening elevation of temperature developed. Physical examination was unchanged except for a slight increase in the size of the enlarged lymph nodes. Biopsy of a cervical node confirmed the clinical diagnosis of Hodgkin's disease and a culture taken of this node yielded *Brucella melitensis var. melitensis*. Admission to the hospital was advised but the patient did not return until Jan. 26, 1939.

The physical condition at this admission was unchanged except for further slight enlargement of the lymph nodes. The temperature was 39.5 C. (103.1 F.), pulse rate 140 and respiratory rate 24. A blood count revealed hemoglobin 62 per cent, red blood cells 3,140,000 and white blood cells 20,000, polymorphonuclear leukocytes 82 per cent (stab cells 53 per cent), eosinophils 1 per cent, basophils 0, large lymphocytes 4 per cent, small lymphocytes 9 per cent, monocytes 4 per cent. Roentgenograms of the chest showed a large mass in the superior mediastinum. Bacteriologic and immunologic studies are given in chart 1.

At bed rest the patient's temperature fell to 37.5 C. (99.3 F.) on the third hospital day, at which time administration of sulfapyridine was started but it was discontinued after one week because of leukopenia. Throughout the administration of sulfapyridine the patient was afebrile, but four days after discontinuation of the drug his temperature rose to 39.5 C. (103.1 F.) and remained elevated for two days. Blood cultures were sterile. Under sulfapyridine therapy there was a progressive and marked decrease in the size of the superficial lymph nodes, and x-ray examination showed marked diminution in the size of the mediastinal mass. A lymph node excised on February 11 again showed the histopathologic picture of Hodg-

kin's disease. A culture taken of this node yielded diphtheroids. The patient had improved greatly by the time of discharge on March 3 and appeared well when visited at home on March 18.

The patient was readmitted to the hospital on May 17, having felt well in the interval. The temperature was 36.8 C. (98.6 F.). There was no recurrent enlargement of the cervical, axillary and right inguinal lymph nodes but there was definite enlargement of the left inguinal and femoral nodes. Hemoglobin was 59 per cent; red blood cells numbered 3,020,000, white blood cells 8,800, polymorphonuclears 52 per cent, eosinophils 2 per cent, basophils 0, large lymphocytes 6 per cent, small lymphocytes 34 per cent and monocytes 6 per cent. Cultures taken of an inguinal node on the left side which gave the pathologic appearance of Hodgkin's disease were sterile. A roentgenogram of the chest showed complete absence of the mass originally noted in the superior mediastinum.

On May 19 sulfapyridine was given but was discontinued on May 27 because of severe nausea and vomiting. On May 22 the patient's temperature, previously not above 37.8 C. (100 F.), rose to 39 C. (102 F.) and remained elevated for four days. At this time *Brucella melitensis var. melitensis* was isolated from the blood. Ten cc. of bovine antimelitensis serum was given intramuscularly on May 24 and 25, with a subsequent prompt fall of temperature to normal. The left inguinal and

Chart 1.—Bacteriologic and immunologic studies in case 2.

femoral lymph nodes gradually decreased in size. On May 29 the patient complained of generalized itching of the skin and a mild exfoliative dermatitis developed. He was discharged from the hospital greatly improved on June 4.

The patient was readmitted to the hospital on September 8. He had been well until one week previously, when an evening fever developed and recurrent enlargement of the left cervical, axillary and inguinal lymph nodes. The temperature was 37.4 C. (99.3 F.). The patient did not appear ill. The firm, nontender cervical nodes were barely palpable. In the left axilla was a mass of firm, nontender nodes measuring 5 by 6 cm. The inguinal nodes were similarly enlarged. A large, firm, nontender mass measuring 6 by 6 cm. was felt over the right external iliac vessels. On rectal examination a similar smaller mass was felt on the left side.

Examination of the blood revealed hemoglobin 58 per cent, red blood cells 2,750,000, white blood cells 5,200, polymorphonuclears 44 per cent (stab cells 3 per cent), eosinophils 2 per cent, basophils 0, large lymphocytes 3 per cent, small lymphocytes 36 per cent, monocytes 15 per cent. The corrected sedimentation rate was 28 mm. per hour. A roentgenogram of the chest showed no mediastinal or hilar enlargement.

An elevation of temperature to 38.6 C. (101.5 F.) was noted on the second hospital day. Thereafter the patient was afebrile for one week, when the temperature rose to 38.2 C. (100.7 F.). At this time sulfapyridine was given for one week, during which time the fever promptly ceased and there was marked

regression of lymph node enlargement by the time of discharge on September 23.

The patient returned to the hospital on Feb. 2, 1940. In the interval he had had occasional episodes of fever and malaise lasting several days. One week before his return there was transient enlargement of the left cervical lymph nodes.

The temperature was 37.4 C. (99.3 F.). The left cervical lymph nodes were firm and nontender and measured from 2 to 3 cm. in diameter. The right cervical, axillary and inguinal nodes were smaller, firm and nontender. On rectal examination a few small, firm nodes were palpable on the left.

Examination of the blood revealed hemoglobin 68 per cent, red blood cells 3,760,000, white blood cells 12,600, polymorphonuclears 69 per cent (stab cells 1 per cent), eosinophils 1 per cent, basophils 0, large lymphocytes 2 per cent, small lymphocytes 27 per cent, monocytes 1 per cent; corrected sedimentation rate 28 mm. per hour. A roentgenogram of the chest was not remarkable.

During the patient's hospital stay there was an occasional elevation of temperature to 37.7 C. (99.8 F.). No treatment was given and the patient's condition was unchanged at discharge on February 11.

The initial marked regression of the widespread enlargement of lymph nodes under sulfapyridine therapy in this case was striking. It is noteworthy that the

Chart 2.—Bacteriologic and immunologic studies in case 3.

appearance of serum agglutinins and marked phagocytosis coincided with this clinical improvement. Subsequently *Brucella melitensis* var. *melitensis* was isolated from blood cultures, taken during a febrile episode and shortly after recurrent enlargement of the left inguinal and femoral lymph nodes. After administration of antimelittensis serum and sulfapyridine there was prompt subsidence of fever and lymph node enlargement. No evidence of an immune response existed at the time *Brucella melitensis* var. *melitensis* was isolated from the blood, nor has there been any significant immune response during subsequent periods of activity of the disease process. The clinical course, which has appeared to be influenced by treatment directed toward control of the *Brucella* infection, can be correlated closely enough with the cultural and immunologic observations to suggest that a great part of the clinical picture presented by this patient with Hodgkin's disease might be explained by the coexisting *Brucella* infection.

CASE 3.—Left supraclavicular lymph node enlargement; roentgen therapy; fever and enlargement of liver and spleen, isolation of *Brucella melitensis* var. *melitensis* from lymph node and blood cultures; treatment with sulfapyridine; death one year after onset.

S. G., a white man aged 38, admitted to the hospital Jan. 20, 1939, complained of abdominal pain of five weeks' duration.

His illness began in April 1938 with a gradual onset of weakness, painless progressive enlargement of the left supraclavicular lymph nodes and intermittent sharp pain in the lower part of the abdomen radiating to both lumbar regions. A loss of weight of from 20 to 30 pounds (9 to 13.6 Kg.) occurred during the first month of illness. Roentgen therapy was given to the left supraclavicular region during April and May 1939, with prompt regression of lymph node enlargement and improvement in the patient's general condition. The patient was relatively well and able to work until December 1938, when so-called flu developed, with malaise, fever and night sweats. At this time severe "knifelike" para-umbilical pain, radiating to both lumbar regions, appeared and persisted.

The temperature was 38.5 C. (101.3 F.), pulse rate 104, respiratory rate 22 and blood pressure 110 systolic, 72 diastolic. The patient was malnourished and appeared chronically ill. Small, firm, nontender cervical and axillary nodes were palpable on the left side. There was no other enlargement of the lymph nodes. The abdomen was distended and tympanitic but not tender. The liver edge was percussed 3 cm. below the costal margin. The spleen was palpable at the costal margin.

Wassermann and Kahn reactions of the blood were negative; hemoglobin was 61 per cent; red blood cells numbered 3,570,000, white blood cells 5,900, polymorphonuclears 85 per cent (stab cells 2 per cent), eosinophils 1 per cent, basophils 0, large lymphocytes 4 per cent, small lymphocytes 3 per cent and monocytes 7 per cent. The corrected sedimentation rate was 24 mm. per hour; roentgenographic examinations of the chest and gastrointestinal tract were negative except for an inconstant defect of the duodenal cap thought to be due to extrinsic pressure. Histologic section of an axillary lymph node showed lymphadenitis suggestive of Hodgkin's disease and cultures taken of this node yielded *Brucella melitensis* var. *melitensis*. Bacteriologic and immunologic studies are given in chart 2.

At rest in bed the patient's temperature varied between 38 and 39 C. (100.4 and 102 F.). Administration of sulfapyridine was started on February 7 but was discontinued on March 1 because of leukopenia and anemia. During sulfapyridine therapy the patient became afebrile, the abdominal pain disappeared and the liver and spleen decreased in size. Cultures taken of a lymph node excised on March 8 were sterile. This node again showed a histopathologic picture suggestive of Hodgkin's disease. The patient was much improved at the time of discharge, March 11, although for the three preceding days an elevation of temperature to 38.4 C. (101.1 F.) was noted.

The patient remained well for one week and then an infection of the upper respiratory tract developed, following which he became acutely ill and was readmitted to the hospital April 15.

The temperature was 38.9 C. (102 F.), pulse rate 124, respiratory rate 24, and blood pressure 110 systolic, 80 diastolic. The patient was markedly emaciated and acutely ill. The essential physical conditions were unchanged.

Hemoglobin was 60 per cent, red blood cells numbered 3,000,000, white blood cells 12,320, polymorphonuclears 92 per cent (stab cells 7 per cent, juveniles 1 per cent), eosinophils 0, basophils 0, large lymphocytes 3 per cent, small lymphocytes 3 per cent, monocytes 2 per cent. The corrected sedimentation rate was 26 mm. per hour. A roentgenogram of the chest showed no significant change. An examination of the gastrointestinal tract again showed inconstant deformity of the duodenal bulb. *Brucella melitensis* var. *melitensis* was isolated from blood cultures. Sections of an axillary lymph node showed the microscopic appearance of Hodgkin's disease. Cultures taken of this node were grossly contaminated.

The patient's course was characterized by fever and progressive cachexia, terminating in death six weeks after admission. Sulfapyridine was started on the second hospital day and was continued until the day before death. Repeated blood transfusions were given. On May 14, intravenous administration of bovine antimelittensis serum had to be stopped after 20 cc. had been given because of severe pain in the back. Seventeen cc. of blood serum from a person who had recovered from *Brucella* infection was given intravenously on May 20. Signs of focal pneumonia appeared and the patient sank into coma and died May 24.

Necropsy showed Hodgkin's disease involving the spleen, liver, kidneys and all lymph nodes, especially the retroperitoneal

and abdominal nodes. Cultures taken of the liver, a splenic lesion, lungs, pancreas, testicle, bile and of many lymph nodes yielded *Brucella melitensis* var. *melitensis*.

When this patient first came under observation, Hodgkin's disease with extensive abdominal involvement was considered to be the probable diagnosis. It should be emphasized, however, that the diagnosis of Hodgkin's disease was not established until six weeks before death. The histopathologic appearance of the first lymph nodes of which a biopsy was made was suggestive, but conclusive evidence of Hodgkin's disease was not obtained until a third biopsy was made. On the contrary, the presence of *Brucella* infection was demonstrated by isolation of the organism from the first lymph node biopsy five months before death and from subsequent blood cultures. Coincident with this clinical improvement was the appearance of serum agglutinins and marked phagocytosis. However, evidence of immunity to *Brucella* subsequently disappeared during the rapidly progressive phase of the disease, which was characterized by fever, cachexia and bacteremia. At necropsy Hodgkin's disease was widespread, and cultures taken of numerous lymph nodes and of the liver, spleen, pancreas, testicle and bile yielded *Brucella melitensis* var. *melitensis*.

CASE 4.—W. D., a white man aged 31, who entered the hospital Feb. 14, 1939, complained of intermittent fever, malaise and loss of weight of two years' duration. Coincident with the onset of these symptoms a tender swelling was noted in the right cervical region which regressed after roentgen therapy, but the systemic symptoms continued. Several weeks before entry enlargement of the right cervical lymph nodes was noted. Several firm, nontender right cervical nodes, about 2 cm. in diameter, were felt, and there was slight enlargement of the left cervical and axillary nodes. The spleen was palpable at the costal margin. Biopsy of a cervical lymph node established the diagnosis of Hodgkin's disease. Cultures of the nodes were sterile. Under treatment with sulfapyridine there was a definite decrease in the size of the enlarged lymph nodes. This treatment had to be discontinued because of the development of icterus, which persisted. The patient's subsequent course was characterized by Pel-Ebstein fever and progressive cachexia. Death occurred November 22. Permission for necropsy was not obtained. *Brucella melitensis* var. *suis* was isolated from the blood during the last four months of life.

CASE 5.—Generalized pruritus of nine months' duration; right cervical and mediastinal lymph node enlargement; isolation of *Brucella melitensis* var. *suis* from blood and lymph node cultures; treatment with sulfapyridine; no improvement.

P. T., a white woman aged 31, who entered the hospital on Feb. 18, 1939, complained of generalized pruritus of nine months' duration. No cutaneous lesions other than scratch marks had been noted. Three weeks before admission she noticed prominence of a vein in the left side of her neck. A loss of 10 pounds (4.5 Kg.) had occurred.

On physical examination the temperature was 36.9 C. (98.4 F.), pulse rate 110, blood pressure 124 systolic, 82 diastolic. The patient was malnourished but did not appear ill. The skin was rough and dry; no lesions were noted. In the right cervical region a firm, nontender mass of lymph nodes, each about 1 cm. in diameter, was felt. Elsewhere there was no enlargement of the lymph nodes. The left external jugular vein was greatly distended. The chest and abdomen were not remarkable.

Wassermann and Kahn reactions of the blood were negative; hemoglobin was 77 per cent; red blood cells numbered 3,880,000 and the white blood cells 10,150, polymorphonuclears 67 per cent, eosinophils 8 per cent, basophils 0, large lymphocytes 5 per cent, small lymphocytes 8 per cent, monocytes 12 per cent; a roentgenogram of the chest showed a large mass in the superior mediastinum. A specimen taken from a right cervical lymph node for biopsy confirmed the diagnosis of Hodgkin's

disease. *Brucella melitensis* var. *suis* was isolated from this node and from the blood. Immunologic studies are given in chart 3.

The patient was afebrile throughout her hospital stay. Sulfapyridine was given daily in doses up to 4 Gm. She was discharged March 10 but was closely followed and continued to take sulfapyridine. By March 27 there had been a definite reduction in the size of the right cervical nodes and pruritus had lessened. X-ray examination showed no change in the size of the mediastinal mass. Sulfapyridine was discontinued on April 3.

The patient returned on April 19 complaining of intensified pruritus of four days' duration. Physical examination was unchanged except for enlargement of a single, firm, nontender lymph node just above the right clavicle. A roentgenogram showed no change in the size of the mediastinal mass. Admission to the hospital for further treatment was advised but the patient refused. Sulfapyridine was taken irregularly from April 22 to April 30. The patient's condition was unchanged when last seen, May 1, 1939.

In this case there was definite reduction in the size of the enlarged right cervical lymph nodes under sulfapyridine therapy and pruritus improved, although no actual decrease in the size of the mediastinal mass could

Chart 3.—Bacteriologic and immunologic studies in case 5.

be demonstrated roentgenologically. Serum agglutinins and significant degrees of phagocytosis appeared during the course of therapy but were not well sustained and were completely lacking with the recurrence of superficial lymph node enlargement, intensified pruritus and bacteremia. At this time *Brucella melitensis* var. *suis* was isolated from the heart's blood of two guinea pigs, which died nine days after intraperitoneal injection of 2 cc. of the patient's citrated blood.⁶

CASE 6.—C. I., a white woman aged 49, complained that in June 1938 fatigability and intermittent fever developed, with gradual painless enlargement of the superficial lymph nodes. Examination in January 1939 revealed marked enlargement of cervical, axillary, mediastinal and inguinal lymph nodes, and the liver and spleen were palpable. Biopsy of a lymph node established the diagnosis of Hodgkin's disease. Under roentgen therapy enlargement of the lymph nodes disappeared, the spleen and liver were no longer palpable and the fever subsided. She entered the hospital two weeks after completion of the roentgen therapy. Several firm, nontender cervical nodes on the right, from 2 to 3 cm. in diameter, were palpable. An excised lymph node showed marked fibrosis attributed to roentgen therapy and a culture taken of this node yielded *Streptococcus viridans*. The patient was closely followed and on May 1 slight enlargement of a right cervical node and an elevation of temperature

6. Poston, Mary A.: Studies on Chronic Brucellosis: III. Methods Used in Obtaining Cultures, Pub. Health Rep. 53:1-4 (Jan. 7) 1938.

were noted. *Brucella melitensis* var. *melitensis* was isolated from a blood culture taken on May 27, 1939. The patient was readmitted to the hospital June 6. There were daily elevations of temperature to 37.9 C. (100.2 F.), the spleen was palpable but there was no further enlargement of the lymph nodes. Under treatment with sulfapyridine and bovine anti-melitensis serum the fever subsided, the cervical lymph nodes decreased in size and the spleen was no longer palpable at the time of discharge, June 15. Repeated blood cultures were sterile. Since this time there has been no evidence of activity of the Hodgkin's disease process.

CASE 7.—Generalized pruritus with intermittent left cervical and axillary lymph node enlargement of three years' duration; initial treatment with sulfapyridine; recurrence of lymph node enlargement with stomatitis; cultures taken of oral lesions and of blood yielded *Brucella melitensis* var. *melitensis*; treatment with sulfapyridine and immunotransfusion; subsequent recurrence of cervical and axillary lymph node enlargement, appearance of mediastinal enlargement and fever; temporary improvement under roentgen therapy.

M. T., a white woman aged 31, first visited the hospital Nov. 4, 1937, complaining of generalized itching of one year's duration. Her illness began in the autumn of 1936 with persistent generalized itching and no cutaneous lesions other than excoriations caused by scratching. There had been progressive

22 and blood pressure 142 systolic, 80 diastolic. The patient was malnourished but did not appear ill. She constantly scratched all parts of her body, over which the skin was thickened, dry, a light brown and covered with numerous excoriations. The firm, nontender cervical lymph nodes, particularly those on the left, were enlarged to from 2 to 3 cm. in diameter. The left axillary nodes were enlarged to a slightly less degree. Elsewhere the superficial lymph nodes were barely palpable. The heart and lungs were not remarkable. There was no abdominal tenderness and no organs or masses were felt.

The Wassermann and Kahn reactions were negative; a blood count revealed hemoglobin 78 per cent, red blood cells 4,200,000, white blood cells 14,040, polymorphonuclears 76 per cent, eosinophils 11 per cent, basophils 1 per cent, large lymphocytes 4 per cent, small lymphocytes 6 per cent, monocytes 2 per cent. A roentgenogram of the chest was negative. Biopsy of a cervical lymph node confirmed the diagnosis of Hodgkin's disease. Cultures of the node were sterile. Bacteriologic and immunologic studies are given in chart 4.

Sulfapyridine was started on March 9 and was continued throughout her hospital stay. An occasional elevation of temperature to 38.5 C. (101.3 F.) was noted. The enlarged lymph nodes had decreased markedly in size and pruritus was much improved by the time of discharge, April 4.

For two weeks preceding her return on April 24 the patient noted a gradual recurrence of all her symptoms. The tempera-

ture was 37.2 C. (98.9 F.), pulse rate 90 and respiratory rate 20. The only change in her physical manifestations related to the size of the lymph nodes. The firm, discrete and nontender left cervical and axillary nodes were again enlarged, being from 2 to 3 cm. in diameter. The right cervical and axillary nodes were enlarged to a lesser degree. Hemoglobin was 81 per cent, red blood cells numbered 4,080,000 and white blood cells, 14,400, polymorphonuclears 74 per cent (stab cells 9 per cent), eosinophils 2 per cent, basophils 0, large lymphocytes 2 per cent, small lymphocytes 17 per cent and monocytes 5 per cent. A roentgenogram showed two small areas of density in the right

Chart 4.—Bacteriologic and immunologic studies in case 7.

abdominal enlargement and amenorrhea for the past five months, the patient considering herself pregnant.

The temperature was 37.7 C. (99.8 F.), the pulse rate 80, respiratory rate 20 and blood pressure 110 systolic, 65 diastolic. The patient was well nourished and did not appear ill. Small excoriations were scattered over the dry and scaly skin. No lymph nodes were palpable. Heart and lungs were not remarkable. The abdomen was symmetrically enlarged; the uterine fundus extended 22 cm. above the umbilicus. The clinical impression was neurogenic pruritus accentuated by pregnancy.

The patient returned on March 6, 1939, thirteen months after delivery of a normal fetus at term; she still complained of itching, which had continued with only brief periods of abatement. Enlargement of several left cervical and axillary lymph nodes had been noted for two months. On close questioning it was found that at the onset of her illness in November 1936 the patient had noted a firm, nontender mass the size of "the end of a thumb" in the left side of her neck, and soon afterward similar masses had been felt in the same region and in the left axilla. These masses had fluctuated in size but had been enlarging for the preceding two months. The patient had not given this history at the time of her first visit in November 1937 because she considered it of no significance. During the preceding year she had noticed thickening, dryness and slight darkening of her skin, a loss of 20 pounds (9 Kg.), and increasing fatigability and nervousness. There had been no return of the menses following parturition.

She was admitted to the hospital March 8, 1939. The temperature was 37 C. (98.6 F.), pulse rate 110, respiratory rate

midlung field. Biopsy of a cervical lymph node revealed the histopathologic picture of Hodgkin's disease. Cultures of this node were sterile.

The patient was followed at short intervals until readmission to the hospital was possible. Administration of sulfapyridine, started on April 26, was attended by nausea and occasional vomiting. No change occurred in the size of the enlarged lymph nodes up to the time of readmission on May 7. Fever was absent during this period. A repeated roentgenogram of the chest on May 8 showed a slight decrease in the size of the densities in the right midlung field. On May 9 an elevation of temperature to 38 C. (100.4 F.) occurred and the patient complained of soreness of the mouth. Over the gums, buccal surfaces and hard palate were numerous irregularly outlined, white, adherent patches of exudate surrounded by hyperemic mucosa and measuring from 1 mm. to 1 cm. in diameter. The anterior pillars were reddened, but no lesions were noted in the pharynx. Cultures taken of material from the oral lesions yielded *Streptococcus viridans*, *Neisseria sicca* and *Brucella melitensis* var. *melitensis*. There was no growth on Sabouraud's medium and no spirochetes were seen on dark field examination of material from the lesions. *Brucella melitensis* var. *melitensis* was isolated from blood cultures at this time. The patient's temperature did not rise above 38.3 C. (100.9 F.). On May 11 a transfusion of 500 cc. of blood was given, the donor of which had *Brucella* agglutinins in high titer. On the following day the patient became afebrile and sulfapyridine, refused by the patient for the preceding two days, was resumed. The oral lesions disappeared in eight days and progressive diminution

in the size of the lymph nodes was noted. Blood cultures became sterile and the patient was discharged much improved on May 21. Sulfapyridine was continued for five days.

The patient returned on June 20 complaining of weakness and severe pruritus. It was thought that there had been an increase in the size of the cervical and left axillary nodes. She was readmitted to the hospital July 18, complaining of further enlargement of the lymph nodes, severe pruritus and weakness. She had had no known fever, and no loss of weight had occurred. For the preceding two weeks she had had a nonproductive, paroxysmal cough when lying on her back and a feeling of "tightness" on swallowing.

The temperature at this time was 37.8 C. (100 F.), pulse 80 and respiratory rate 20. The patient appeared chronically ill. Numerous discrete, firm, nontender lymph nodes from 1 to 2 cm. in diameter filled the left anterior and posterior cervical regions. Single nodes of similar size were felt in the submental region and above the suprasternal notch. A few small cervical nodes were felt on the right. In the left axilla a large mass of variously sized nodes measured 8 by 8 cm. The right axillary, epitrochlear and inguinal nodes were slightly enlarged. Examination of the heart and lungs was not remarkable. The firm, nontender liver edge was felt 3 cm. below the costal margin; the spleen was not felt.

A blood count revealed hemoglobin 72 per cent, red blood cells 3,320,000, white blood cells 18,800, polymorphonuclears 88 per cent (stab cells 11 per cent, juveniles 1 per cent), eosinophils 1 per cent, basophils 0, large lymphocytes 2 per cent, small lymphocytes 5 per cent and monocytes 4 per cent. A roentgenogram of the chest showed extensive mediastinal and hilar enlargement. Biopsy of a cervical node showed the characteristic signs of Hodgkin's disease; cultures of the node were sterile. Biopsy of the skin showed no definite lesions.

During the first week of the patient's hospital stay there was a daily elevation of temperature to 38.6 C. (101.5 F.), thereafter to 39.4 C. (102.9 F.). On July 22 sulfapyridine was started but had to be discontinued because of nausea and vomiting. Fifty cc. of bovine antimelitensis serum was given intravenously on August 2. On August 3 roentgen therapy to the cervical, mediastinal and upper abdominal regions was started. Her condition was unchanged at the time of discharge on August 10, but subsequently there was a marked decrease in the size of the cervical nodes and subsidence of cough.

The patient has returned for reexamination at intervals of from four to six weeks. Superficial enlargement of the lymph nodes and mediastinal enlargement have been recurrent, and areas of infiltration into the lungs have been demonstrable roentgenologically. Intermittent fever, cough and fatigability have continued. Under roentgen therapy there has been slight temporary improvement in her general condition.

This case is of interest because of the long duration of the disease with a tendency toward localization of the involvement of the lymph nodes. A clinical picture developed indistinguishable from acute brucellosis, and *Brucella melitensis* var. *melitensis* was isolated from blood and oral lesions. Coincidentally there were further enlargement of the lymph nodes and intensified pruritus. Although the stomatitis cleared and blood cultures became negative under treatment with sulfapyridine and immunotransfusion, the patient's general condition became worse and there was rapid and widespread progression of the Hodgkin's disease process.

CASE 8.—Cervical lymph node enlargement of two years' duration; isolation of *Brucella melitensis* var. *suis* from blood and lymph node cultures; treatment with sulfapyridine and immune serum; death three years after onset.

E. D., a Negro boy aged 6 years, was brought to the hospital on April 26, 1938, because of swelling in the right side of the neck of two years' duration. This enlargement of the neck was progressive and associated with intermittent fever of unknown degree. Several weeks before entry increasing weakness, pallidation and shortness of breath developed.

On physical examination the temperature was 39 C. (102 F.), pulse rate 120 and respiratory rate 28. The patient was weak and undernourished but in no acute distress. An enormous S shaped mass filled the entire right cervical region extending 25 cm. from below the ear over the clavicle and onto the shoulder and anterior wall of the chest. This mass was composed of firm, nontender lymph nodes measuring up to 5 cm. in diameter. A similar mass was felt in the left supraclavicular region, measuring about 8 cm. in diameter. There was no other lymph node enlargement. Examination of the chest was not remarkable. The liver was not palpable. The spleen was felt 5 cm. below the costal margin. There was slight edema of the ankles.

The Wassermann and Kahn reactions of the blood were negative; a blood count revealed hemoglobin 29 per cent, red blood cells 1,840,000, white blood cells 3,480, polymorphonuclears 74 per cent, eosinophils 1 per cent, large lymphocytes 4 per cent, small lymphocytes 13 per cent, monocytes 8 per cent. A roentgenogram of the chest showed marked tracheal displacement and a diffuse shadow extending out into the upper portion of the left lung field which could not be differentiated from displacement of the aorta. The enlarged mass in the neck obscured the right upper and middle lung fields. Biopsy of a cervical lymph node showed the histopathologic picture of Hodgkin's disease. *Brucella melitensis* var. *suis* was isolated

Chart 5.—Bacteriologic and immunologic studies in case 8.

from this node and from the blood. Immunologic studies are given in chart 5.

During the first four weeks of the patient's stay in the hospital there was irregular fever reaching 40.1 C. (104.2 F.). Repeated blood transfusions were given. Sulfapyridine was started on May 9 and discontinued on May 22 because of increasing leukopenia. Ten cc. of bovine antimelitensis serum was given intramuscularly on May 16. On May 19, following a blood transfusion from a donor found to have evidence of immunity to *Brucella* infection, the patient's temperature fell promptly and after remaining within normal limits for six days rose again. By May 25 a marked decrease in the size of the enlarged lymph nodes had occurred. Repeated injections of bovine antimelitensis serum on June 6 and June 8 were without demonstrable effect. Roentgen therapy to the cervical and mediastinal regions was started on June 17, resulting in a gradual diminution of fever but without further reduction in the size of the enlarged nodes. The patient appeared to be improved when discharged from the hospital on June 27 but he died quietly at home on June 30, 1939. Permission for necropsy was not obtained.

Treatment with sulfapyridine and immune serum apparently caused a marked reduction in the size of this patient's tremendously enlarged lymph nodes. There was no significant immune response to the *Brucella* infection.

CASE 9.—Intermittent fever; enlargement of the cervical and axillary lymph nodes on the left and hepatomegaly of three months' duration; *Brucella melitensis* var. *melitensis* isolated from blood cultures; treatment with sulfapyridine; recurrence of fever with icterus; treatment with antimelitensis serum; death one year after onset.

P. W., a man aged 29, a mulatto, admitted to the hospital on May 23, 1939, complained of weakness and swelling of the neck of three months' duration. His illness was considered to have started in the spring of 1939 with a gradual onset of anorexia, malaise, loss of weight and the appearance of painless swellings in the left side of the neck and in both axillae. There had been occasional bouts of high fever and recurrent generalized abdominal discomfort with dull aching pain in the lumbar region.

The temperature was 37.1 C. (98.8 F.), pulse 100, respiratory rate 20 and blood pressure 120 systolic and 70 diastolic. The patient was poorly nourished and appeared chronically ill. On the left side of the neck and in the left axilla there were large, firm, movable, nontender masses of lymph nodes measuring 5 by 3 cm. There was no other lymph node enlargement. Examination of the abdomen revealed marked voluntary muscle spasm. The liver extended 8 cm. below the right costal margin and was firm and tender. The spleen was not felt.

Wassermann and Kahn reactions were negative; a blood count revealed hemoglobin 52 per cent, red blood cells 3,490,000,

Sulfapyridine was started on June 24 and continued throughout the patient's hospital stay. Three days later the patient's temperature, previously within normal limits, rose to 40.2 C. (104.3 F.). The patient was febrile for seven days, after which his temperature fell by lysis. Coincident with the fall in temperature there was marked diminution in the size of the enlarged lymph nodes and liver and general improvement in the patient's clinical condition. He was much improved when discharged from the hospital on July 15.

He returned on July 21 complaining of a cutaneous eruption. Four days previously he had noticed a generalized erythematous eruption and pustular lesions in the region of the beard. The temperature was 37.5 C. (99.5 F.). There was a pustular eruption in the beard area and a generalized erythematous eruption with ecchymotic lesions over the distal portions of the extremities. Other physical conditions were unchanged. A blood count revealed hemoglobin 67 per cent, red blood cells 3,120,000, white blood cells 26,200, polymorphonuclears 42 per cent (stab cells 7 per cent), eosinophils 1 per cent, large lymphocytes 7 per cent, small lymphocytes 23 per cent, monocytes 7 per cent and lymphoblasts 19 per cent. It was considered that the patient had a toxic erythema due probably to sulfapyridine.

The patient returned on July 26 saying that the cutaneous eruption had subsided rapidly. But on the evening of the day of his preceding visit generalized abdominal pain and a severe watery diarrhea developed. He had had fever and slight nausea.

He vomited the morning of the day before admission and a dull, aching pain and extreme soreness in the right upper quadrant developed.

The temperature was 39.8 C. (103.6 F.), pulse rate 120 and respiratory rate 22. The scleras were slightly icteric. A few small, firm lymph nodes were felt in the cervical and left axillary regions. In the right axilla there was a large mass of recently enlarged nodes, each about 1 cm. in diameter. No epitrochlear nodes were felt. The inguinal nodes were barely palpable. The heart and lungs were not remarkable. There was rigidity, exquisite tenderness and rebound tenderness in the right upper quadrant of the abdomen. Elsewhere there was no muscle spasm or tenderness. The liver could not be palpated because of muscular rigidity. The spleen was not felt. No masses were felt. Rectal examination gave negative results.

The white blood cells numbered 8,700, polymorphonuclears 74 per cent (stab cells 5 per cent), eosinophils 0, basophils 0, large lymphocytes 5 per cent, small lymphocytes 16 per cent and monocytes 5 per cent. The van den Bergh reaction was direct; serum bilirubin was 3.8 mg. per hundred cubic centimeters.

The condition was considered related to abdominal Hodgkin's disease and the patient was admitted for observation. The day following entry the abdominal signs disappeared. He remained acutely ill with daily elevations of temperature to 40 C. (104 F.) until August 15, at which time he became afebrile and a rapid and marked improvement in his general condition followed. Fifty cc. of bovine antimelitensis serum was given intravenously on August 8. By the time of discharge, August 18, jaundice had disappeared, the enlarged lymph nodes had decreased in size and the spleen and liver were not felt.

The patient was readmitted to the hospital on December 11. In the interval weakness had been progressive and he had had intermittent fever and pain in the right upper quadrant.

The temperature was 38.2 C. (100.7 F.), pulse rate 116 and respiratory rate 30. The patient was pale and extremely emaciated and appeared gravely ill. There was slight icterus of the scleras. The left cervical and axillary nodes were firm, nontender and from 2 to 3 cm. in diameter. Expansion of the chest was poor. Over the right posterior part of the chest there was a palpable and audible friction fremitus with impairment of the percussion note and diminished breath and voice sounds. A systolic murmur was heard over the precordium. The abdomen was distended and the liver dullness extended

Chart 6.—Bacteriologic and immunologic studies in case 9.

white blood cells 6,700, polymorphonuclears 85 per cent (stab cells 23 per cent), eosinophils 0, basophils 0, large lymphocytes 2 per cent, small lymphocytes 4 per cent, monocytes 9 per cent. A roentgenogram of the chest showed moderately dense masses at the pulmonary hili which were considered to be enlarged lymph nodes. Bacteriologic and immunologic studies are given in chart 6.

The patient returned May 30, saying that he had had a mild infection of the upper respiratory tract and believed that he had had intermittent fever. The temperature was 39.7 C. (103.4 F.), pulse 112, respiratory rate 24. There was no significant change in the physical examination.

He was admitted to the hospital on June 21. In the interval he had continued to have intermittent fever, malaise and progressive loss of weight.

The temperature was 37.4 C. (99.3 F.), pulse 86, respiratory rate 20 and blood pressure 118 systolic and 74 diastolic. There was no change in the physical condition except for marked enlargement of the right axillary lymph nodes.

A blood count revealed hemoglobin 73 per cent, red blood cells 3,920,000, white blood cells 8,200, polymorphonuclears 79 per cent (stab cells 7 per cent), eosinophils 0, basophils 1 per cent, large lymphocytes 6 per cent, small lymphocytes 12 per cent, monocytes 2 per cent. A roentgenogram of the chest showed no change. A roentgenogram of the abdomen showed that the liver extended to the iliac crest. Biopsy of a cervical node revealed the histopathologic changes of Hodgkin's disease; node cultures were sterile.

to the level of the umbilicus. The spleen was palpable at the costal margin.

A blood count revealed hemoglobin 24 per cent, red blood cells 1,600,000, white blood cells 5,160 with polymorphonuclears 77 per cent (stab cells 5 per cent, juveniles 2 per cent), eosinophils 2 per cent, basophils 0, large lymphocytes 6 per cent, small lymphocytes 7 per cent, monocytes 8 per cent; urine and stool examinations gave negative results; the van den Bergh reaction was direct; plasma bilirubin was 1.4 mg. per hundred cubic centimeters. A roentgenogram of the chest showed the right lung obscured. The patient's course was characterized by fever, reaching 40 C. (104 F.) and progressive cachexia. Treatment was entirely symptomatic. Death occurred on Feb. 14, 1940.

Necropsy showed Hodgkin's disease involving the spleen, liver, adrenals, kidneys, bone marrow and lymph nodes, with compression of the common duct and partial obstruction. From necropsy cultures taken in triplicate *Brucella melitensis* var. *melitensis* was isolated from the liver and spleen. Diphtheroids were isolated from a mediastinal node.

Coincident with this patient's initial clinical improvement under sulfapyridine therapy was the appearance of serum agglutinins and increased phagocytosis. Phagocytosis was maintained during a succeeding febrile episode, but all evidence of an immune response was lacking during the terminal phase of the disease.

CASE 10.—C. B., a Negro woman aged 35, who entered the hospital on June 19, 1939, began in January 1939 to have painless, progressive enlargement of the left axillary lymph nodes, malaise and loss of weight. For six weeks preceding entry she had had fever. A firm, nontender, left cervical node, about 2 cm. in diameter, and a left axillary node, about 6 cm. in diameter, were palpable. Biopsy of an axillary node from the left side showed the histopathologic signs of Hodgkin's disease. Cultures taken of the nodes were sterile. *Brucella melitensis* var. *melitensis* was isolated from a blood culture taken on entry. The patient was febrile throughout her hospital stay and there was no significant improvement under treatment with sulfapyridine and bovine antimelitensis serum or roentgen therapy. Following discharge on August 12 febrile episodes continued, anemia became marked and death occurred in December. Permission for necropsy was not obtained.

CASE 11.—A. A., a white woman aged 40, admitted to the hospital on June 27, 1939, complained of weakness, loss of weight and enlargement of the neck of seven months' duration. Above the suprasternal notch and in the right cervical region were firm, nontender masses of enlarged lymph nodes measuring 5 by 4 cm. The spleen was palpable at the costal margin. A roentgenogram of the chest showed a large mediastinal mass. Biopsy of a cervical lymph node confirmed the diagnosis of Hodgkin's disease, and culture taken of this node and blood culture yielded *Brucella melitensis* var. *suis*. There was a moderate decrease in the size of the cervical and mediastinal lymph nodes under roentgen therapy.

CASE 12.—W. H., a Negro aged 64, admitted to the hospital July 7, 1939, complained of enlargement of the neck of six months' duration. In January 1939 the patient noted a nontender mass beneath the angle of the right jaw. Gradually numerous firm, nontender nodules appeared in both cervical regions which increased to a size sufficient to cause difficulty in rotating the neck. Transient regression of this enlargement had been noted. At the time of entry the anterior and posterior cervical lymph nodes were markedly enlarged, firm and nontender and measured from 1 to 3 cm. in diameter; the epitrochlear and inguinal nodes were barely palpable. Biopsy of a cervical lymph node showed the histopathologic signs of Hodgkin's disease. Cultures of the nodes were sterile. Roentgen therapy was given over the cervical region with prompt regression of enlargement of the lymph nodes, which has not recurred. On October 27, *Brucella melitensis* var. *suis* was isolated from a blood culture.

CASE 13.—W. M., a white man aged 37, who entered the hospital Nov. 16, 1939, began to be ill in the summer of 1936 with fatigability, loss of weight and pruritus. In September 1937 painless, slight enlargement of several cervical and inguinal lymph nodes was noted, and biopsy established the diagnosis

of Hodgkin's disease. In January 1938 enlargement of cervical, axillary and inguinal lymph nodes was noted and a roentgenogram of the chest showed widening of the mediastinum. Fever was present at this time. Under roentgen therapy the size of the lymph nodes regressed, fever subsided and the patient's general condition improved. There was subsequent recurrent enlargement of various groups of superficial lymph nodes which regressed promptly under roentgen therapy. The patient was relatively well until June 1939, when daily elevation of temperature and marked fatigability became established, but there was no recurrence of enlargement of the lymph nodes. *Brucella melitensis* var. *melitensis* was isolated from blood cultures taken on entry to the hospital. Under treatment with sulfanilamide and rabbit antimelitensis serum the patient became afebrile and gained in weight. Subsequently fever returned and a flaccid paralysis of the lower extremities developed with a sensory level at the eighth thoracic segment. Since this time his course has been characterized by fever and progressive cachexia.

CASE 14.—*Intermittent cervical lymph node enlargement regressing under roentgen therapy; hilar lymph node enlargement, fever and development of hepatosplenomegaly with ascites; death seven years after onset; Brucella melitensis* var. *suis* isolated in cultures taken post mortem of liver, spleen and peritoneal fluid.

G. B., a Jewish boy aged 13 years, who entered the hospital on Jan. 24, 1940, began to be ill in the spring of 1933 with enlargement of a left cervical lymph node, which subsided promptly after roentgen therapy. In July 1933 there had been recurrent enlargement of the lymph nodes in the same region, which again regressed after roentgen therapy but recurred in several months. In April 1936 biopsy of a cervical lymph node showed the histopathologic signs of Hodgkin's disease. The patient had no systemic symptoms until the fall of 1938, when fever, anorexia, marked fatigability and a dull aching pain developed in the upper

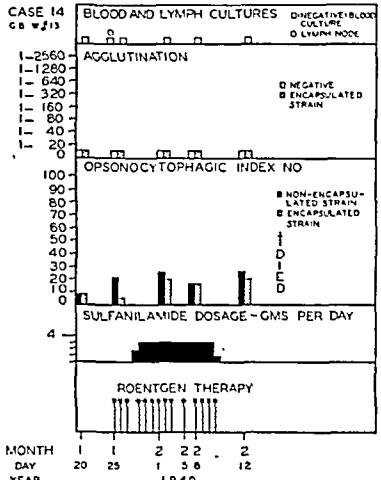

Chart 7.—Bacteriologic and immunologic studies in case 14.

part of the abdomen. At this time tachycardia, splenic enlargement and slight anemia were noted. In January 1939 a roentgenogram of the chest showed large hilar masses. Roentgen therapy was given over the chest and abdomen with temporary improvement. In July 1939 the patient was given sulfanilamide for one week, during which time the spleen decreased in size and improvement of anemia was noted but weakness continued. In November marked dyspnea developed on exertion with cyanosis and loud wheezing, which subsided after roentgen therapy over the mediastinum and upper part of the abdomen. The liver and spleen were palpable at this time and ascites was slowly accumulating. A daily elevation of temperature to 39 C. (102.2 F.) became established and loss of weight, weakness and anemia increased.

The temperature was 38.1 C. (100.6 F.), the pulse rate 130, respiratory rate 32 and blood pressure 120 systolic, 74 diastolic. The patient was pale and emaciated and appeared chronically ill. On the left side single, firm, nontender, cervical and axillary lymph nodes, about 2 cm. in diameter, were felt, as well as many smaller supraclavicular nodes. The inguinal nodes were barely palpable. The chest expanded poorly and there was dullness to flatness posteriorly on the left below the level of the sixth thoracic spine and anteriorly below the level of the fifth rib. The breath and voice sounds were diminished to absent over this area. The heart was enlarged and a systolic murmur was heard over the apex, which was transmitted to

the base. The abdomen was distended and there was shifting dullness in the flanks and a frank fluid wave. The liver edge was felt 9 cm. below the costal margin, firm and nontender. The spleen was felt 14 cm. below the costal margin, firm and moderately tender. Large external hemorrhoids were present. There was slight pitting edema over the dorsum of both feet.

Wassermann and Kahn reactions were negative; hemoglobin was 54 per cent, red blood cells numbered 2,850,000 and white blood cells 7,800, with polymorphonuclears 89 per cent (stab cells 1 per cent), eosinophils 0, basophils 0, large lymphocytes 0, small lymphocytes 5 per cent and monocytes 6 per cent. A roentgenogram of the chest revealed a shadow of uniform density over the lower left lung field and exaggerated hilar markings. Biopsy of a lymph node showed the histopathologic changes of Hodgkin's disease. Cultures taken of the nodes were sterile. Bacteriologic and immunologic studies are given in chart 7.

During the first week in the hospital the patient's temperature varied between 37.6 and 39.9 C. (99.5 and 103.8 F.); thereafter it gradually became lower and did not rise above 38 C. (100.4 F.). Roentgen therapy was given over the spleen, upper part of the abdomen and long bones. Repeated transfusions were given and iron and liver extract were administered, but anemia was progressive. On the fifth hospital day sulfanilamide was started in small doses. The patient became progressively weaker, increasing anemia rapidly developed and death occurred on February 18.

Necropsy showed Hodgkin's disease involving the spleen, liver, diaphragm, pleuras, adrenals and all lymph nodes. *Brucella melitensis* var. suis and diphtheroids were isolated from triplicate cultures taken of material from the spleen, liver and peritoneal fluid at necropsy. Diphtheroids were also isolated from a mesenteric lymph node.

During the terminal phase of this patient's disease there was no evidence of an immune response toward the *Brucella* infection which was shown to exist at necropsy.

COMMENT

The demonstration of *Brucella* infection in fourteen consecutive cases of Hodgkin's disease raises questions that can be answered only by further investigation. The obvious question may be raised as to whether the isolation of this organism from patients with Hodgkin's disease represents merely latent *Brucella* infection or whether it may be of etiologic significance. It is true that the majority of these fourteen patients were natives of an area in which *Brucella* infection is widespread, but if our observations represent merely a latent infection peculiar to this region one should expect to obtain positive cultures with equal frequency from lymph nodes obtained from other patients suffering from chronic diseases involving the lymphatic system. Such has not been the case, despite repeated study of a much larger group of patients with diseases such as lymphosarcoma, leukemia, tuberculous adenitis and the like. *Brucella* has been isolated only once from cultures of sixty-seven lymph nodes removed from patients not suffering from Hodgkin's disease.² From such patients repeated blood cultures have been negative with one exception. On the other hand, *Brucella* has been isolated from blood or lymph nodes on culture, or from both, in these fourteen consecutive cases of Hodgkin's disease. Furthermore, cultures yielding *Brucella* have been obtained with the greatest frequency when Hodgkin's disease was actively progressing, rather than when it was subacute or temporarily arrested.

A sufficient correlation has been found to exist between the cultural and immunologic manifestations and the clinical course of these patients to justify the belief that the *Brucella* infection directly influences the syndrome of Hodgkin's disease. The frequent lack of all evidence of an immune response when *Brucella* could be isolated from blood cultures during recurrences of

Hodgkin's disease has been very striking. Maximum clinical improvement in these fourteen cases has coincided with the presence of serum agglutinins and significant degrees of phagocytosis for *Brucella*.

Although the observations reported here suggest the possible etiologic importance of *Brucella* in the Hodgkin's disease process, the rigid postulates of Koch have not been fulfilled. It has been possible to induce disease leading to death in guinea pigs and mice by intraperitoneal injection of blood or by a suspension of lymph nodes from patients with Hodgkin's disease and to recover *Brucella* subsequently from the blood or tissues of these animals, but lesions identical with those of Hodgkin's disease have not been observed. This phase of the problem is being investigated by the department of pathology and will be reported on later.

Treatment of these fourteen patients has been directed primarily toward the existing *Brucella* infection as a further means of studying the influence of such infection on the course of Hodgkin's disease. A definite and often striking decrease in the size of enlarged lymph nodes has been observed after administration of sulfanilamide or sulfapyridine. Immune serum therapy, utilizing whole blood or blood serum from persons recovered from brucellosis or having serum agglutinins in high titer, or a commercial antiserum, has been combined with sulfanilamide or sulfapyridine, but the effectiveness of these serums has not been demonstrated. Since recent investigations in this laboratory have shown that *Brucella* organisms isolated from many of the patients suffering from Hodgkin's disease possess capsules and show significant antigenic differences from the laboratory strains, further consideration must be given to the antibody properties of the serums used in the treatment of *Brucella* infections.

SUMMARY

The coexistence of *Brucella* infection and Hodgkin's disease has been demonstrated in fourteen consecutive cases by the isolation of *Brucella melitensis* from blood or lymph node cultures. *Brucella* has been isolated but once from blood or lymph node cultures from a much larger group suffering from diseases involving the lymph nodes other than those with Hodgkin's disease. Although the data in this study do not establish an etiologic relationship of *Brucella* to Hodgkin's disease, it is suggested that the clinical course of Hodgkin's disease may be significantly influenced by *Brucella* infection.

Circumventing Our Conflicts.—It may be profitable to examine briefly a few of the devices we tend to employ for the purpose of circumventing our conflicts. . . . Projection is a psychological expedient that seeks to circumvent the hard realities of our conflicts by shifting the blame we should accept ourselves upon others or upon the conditions of life. Projection is common, and in its milder exhibitions it is harmless enough. For instance, the batter strikes out, throws down his bat, and says that the umpire needs glasses; the college girl says that the professor must have looked over the papers very hastily or she would have been credited with a perfect paper; the housewife complains that the baking powder was inferior in quality or the biscuits would have risen. But if practiced too frequently and with too much facility, projection readily becomes a grave menace to the integrity of the personality and the peace of the mind. Soon it erects an impassable barrier between the individual and the possibility of seeing himself as he really is. The descent may be very rapid—excessive criticism, pessimism, sarcasm, cynicism, prejudice, intolerance, hatreds, brooding. And from here it is not a very long step into the territory of mental disease—ideas of reference, hallucinations, delusions of persecution.—Strecker, Edward A., *The Man and the Mob, Mental Hygiene* 24:529 (Oct.) 1940.

DIFFERENTIAL DIAGNOSIS OF VARIOUS
FORMS OF ENCEPHALITIS

JOHN A. TOOMEY, M.D.

CLEVELAND

Sleeping sickness is not the only type of encephalitis. There are many other encephalitides, complexes which are not easily differentiated from one another, complexes which result from a combination of degenerative and disseminated inflammatory changes in the brain, spinal cord and meninges. The lesions of encephalitis are sometimes spotty and scattered, and sometimes generalized. At times the spread of the disease in the central nervous system may be slow and at other times rapid. Therefore diverse signs and symptoms are seen. An encephalitic condition may even have different stages, each stage presenting its own signs, signs which may be referable to the motor, sensory, reflex or autonomic systems and, from an anatomic standpoint, present cerebral, basal ganglionic, bulbar, spinal or meningeal symptoms.

CLASSIFICATION OF ENCEPHALITIDES

A. Encephalitides which occur secondary to or accompany some acute infection:

1. Cerebrospinal fever, chickenpox, dysentery, bacterial endocarditis, herpes zoster, malaria, measles, German measles, mumps, pneumonia, purpura, scarlet fever, puerperal sepsis, smallpox, syphilis, tonsillitis, tuberculosis, typhoid, typhus, undulant fever, whooping cough and any infectious disease of the brain.

2. Usually these include the hemorrhagic types of encephalitis.

B. Encephalitides which occur secondary to ingestion or injections of alcohol, benzene, carbon monoxide, arsenic, lead, thallium, bismuth and so on.

C. Encephalitides associated with poisonings.

D. Encephalitides, toxic neuropathies or encephalopathies (other than those following specific infections) (other synonyms: diffuse meningo-encephalomyelitis, multiple neuritis, toxic neuronitis, acute disseminated encephalomyelitis, dissociated encephalitis), possibly acute multiple sclerosis.

E. Encephalitides which accompany metabolic disorders, such as uremia and the toxemia of pregnancy.

F. Encephalitides associated with localized swellings inside the brain case, probably pressure or irritative phenomena: pachymeningitis, extradural abscess, fractures, and so on.

G. Encephalitides following injection of an active or passive immune principle: smallpox vaccine, rabies vaccine, antitoxins or antisera (tetanus, diphtheria).

H. Encephalitides caused by specific viruses (other than herpes zoster): Japanese type B encephalitis, St. Louis encephalitis, equine encephalomyelitis, possibly lethargic encephalitis, Australian X disease, polioencephalomyelitis, benign lymphocytic choriomeningitis.

I. Diseases or conditions which simulate encephalitis: caisson disease, convulsions, oculomotor lesions, purulent meningitis, neuroses, acute chorea and vascular lesions in the brain associated with embolus, thrombus or hemorrhage.

DIFFERENTIAL DIAGNOSIS

A. Most of these clinical conditions are easily recognized from the history. Those that are difficult to differentiate at times are St. Louis encephalitis, equine encephalomyelitis, Japanese type B encephalitis, polioencephalomyelitis, lethargic encephalitis, acute benign lymphocytic choriomeningitis, Australian X disease, Schilder's disease (sometimes), disseminated encephalomyelitis (or toxic neuronitis), acute multiple sclerosis as well as tuberculous and syphilitic meningitis. Some of these diseases are new to most physicians; some have appeared only in certain places, yet experience indicates that such localizations are never permanent and all physicians should be conscious of their existence.

B. Differential diagnosis is based on a consideration of (1) appearance, age, sex and fate of the patient; (2) temperature, pulse and respiratory rate; (3) history of the illness, especially as regards onset and chronology of symptoms; (4) neurologic changes; (5) spinal fluid manifestations; (6) results of immunologic tests in animals.

C. There are various types of lesions. Encephalitis usually involves the upper motor neuron; when this occurs, the signs are hyperactive deep tendon reflexes, loss of superficial abdominal reflexes, presence of pathologic reflexes (Babinski, Oppenheim, Chaddock, Stone), spasticity, incoordination of muscles without loss of function, and a normal electrical reaction. Some patients may have one, some all and some none of these signs, despite the fact that the upper motor neuron is usually irritated. Often the signs are absent, and coma and a condition tantamount to cord shock with generalized flaccidity occur. The encephalitic condition may be combined with signs of a lower motor neuron lesion such as flaccidity, diminished reflexes, loss of motor function, atrophy or reaction to degeneration, or a meningeal type of reaction may be produced with a positive Kernig and Brudzinski sign, stiff neck, opisthotonos and hyperactive reflexes.

1. Appearance, age, sex and fate of the patient: The appearance is not indicative, since any type of encephalitis may produce somnolence, choreiform movements, myoclonic spasms or tics. The swiftness and diffuseness of the spread will determine the appearance of the patient when he is first examined. In polioencephalomyelitis there is usually not much lethargy and the encephalitis does not persist long. In tuberculous meningitis the patient is apathetic at first and only after days of illness does he become somnolent and have choreiform or myoclonic movements. In benign lymphocytic choriomeningitis the patient is active. In St. Louis encephalitis he looks extremely ill and may appear somnolent unless the attack is an abortive one, in which case there may be no objective response. The same general remarks hold true for equine encephalomyelitis. Patients ill with Japanese type B encephalitis and Australian X disease may be apathetic or comatose. Patients ill with lethargic encephalitis may look irritable, stuporous or lethargic. Usually but few symptoms accompany the onset of Schilder's disease. Patients ill with disseminated encephalomyelitis and acute multiple sclerosis are usually mentally fit. In syphilitic meningitis the patients, who are usually in the older age groups, may or may not appear ill.

Equine encephalomyelitis, polioencephalomyelitis and Schilder's disease are more apt to occur in children. Fifty per cent of the cases of Australian X disease occur in children under 5 years of age. Japanese type B

and lethargic encephalitis usually are found in older age groups.

More males than females have Australian X disease, and twice as many males as females have Schilder's disease. Tuberculous meningitis occurs in any sex and at any age, most commonly, however, in childhood.

Lethargic encephalitis comes on in the winter and spring time; polioencephalomyelitis, St. Louis encephalitis, Japanese type B encephalitis and Australian X disease in the summer and early fall. (Australian X disease occurs during the summer months in the South-

encephalomyelitis, 66 per cent die. Cerebral irritation caused by poliomyelitis virus is not serious. It is only when this irritation is combined with a bulbar type of palsy that the mortality rises to from 50 to 90 per cent. From 25 to 40 per cent of those ill with lethargic encephalomyelitis die; in Japanese type B encephalitis, 60 per cent or more die; in Schilder's disease, 100 per cent die, death occurring suddenly or eventually as long as ten to twelve years after the initial onset.

2. Temperature, pulse, respiratory rate: Nothing is distinctive about the temperature reactions, although

TABLE 1.—General Information

Type of Disease	Age	Sex	Time	Locale	Mortality
Benign lymphocytic choriomeningitis.....	Any	Any	Any	Any	0
St. Louis encephalitis.....	Any	Any	Summer	In and near vicinity of St. Louis; along streams?	20%
Equine encephalomyelitis	Children mostly	Any	Summer	Where epizootic diseases occur in animals	70%
Japanese type B encephalitis.....	Older people	Any	Summer	Japan	60%
Polioencephalomyelitis	Children especially	Any	Summer	Any	70% with bulbar; 0-3% without
Lethargic encephalitis	3d-4th decade	Any	Winter and spring	Any	25-40%

ern hemisphere.) Tuberculous meningitis will happen during any season.

There may be a history of exposure in tuberculous meningitis and a history of an animal epizootic disease in equine encephalomyelitis. The locale suggests the diagnosis of Australian X, Japanese type B and St. Louis encephalitis.

Only rarely does a patient ill with tuberculous meningitis live; for practical purposes it can be said that the mortality rate is 100 per cent. Patients with benign lymphocytic choriomeningitis recover. The mortality in St. Louis encephalitis ranges from 17 to 22 per cent; in children under 15 years it is 5 per cent. In equine

in tuberculous meningitis there may not be any fever until after the patient has lapsed into somnolence.

A change in the character of the pulse usually depends on the amount of fever, but it may also be influenced by increased pressure on the structures at the base of the brain or by inflammatory involvement of the vagus. Infiltration of the vagus and sixth nerves can be demonstrated in tuberculous meningitis. Biot's type of respiration, alternating apnea and hyperpnea may be produced by increased pressure. When the vagal nerve nuclei are involved, as they are in bulbar polioencephalomyelitis, vagus escapement is the result and a tachycardia together with a slowed but deepened respiratory rate

develops; when there is a marked increase in basilar pressure the pulse may be slowed down.

3. History of illness, onset and chronology of symptoms: An abrupt onset is usually seen in all types of encephalitis save in those associated with tuberculous meningitis and Schilder's disease. The history in syphilitic meningitis is also variable. In tuberculous meningitis the history is almost pathognomonic, relatively asymptomatic at first, gradually progressing to the final

tically comatose and hence not very reactive. Late in the course of tuberculous meningitis, any and every type of neurologic reaction may be found. If there is evidence of an upper motor neuron lesion combined with evidence of a lower motor neuron lesion the latter condition is ignored and a diagnosis of an encephalitis is made unless the paralysis or the lower motor neuron type of lesion is segmental in type, in which case poliomyelitis should be diagnosed.

TABLE 3.—Spinal Fluid Manifestations

Type of Disease	Color	Cells		Pressure	Organisms	Globulin	Sugar	Chlorides
		Number	Type					
Benign lymphocytic choriomeningitis.....	Clear to opaque	100 to 3,000	Lymphocyte	+	—	±	—	No significance

* Of course, patients do not appear comatose and maniacal simultaneously. The plus sign merely indicates that such a condition is possible at some time or another. A plus minus sign indicates that the condition may be present, although usually not.

stage over a period of from seven to twenty-one days. Schilder's disease often extends over a long period of time.

4. Neurologic observations: These are not always helpful, since the nervous system reacts only in certain ways, regardless of the stimulus. One should first ascertain whether an upper motor neuron lesion is present. Theoretically an encephalitis patient should have an upper motor neuron response, but many of the encephalitides so shock the patient, especially in equine encephalomyelitis, as to render him somnolent or prac-

Save for infants under 6 months of age, who rarely show objective neurologic phenomena, signs of meningeal irritation are often present with the various encephalitides. In children the only evidence that there may be trouble is when convulsions, high fever, coma and a bulging fontanel are present.

In the acute stages the Queckenstedt maneuver and the eyeground examination are of little practical value in differential diagnosis save in syphilitic meningitis, in which there may be a neuritis and atrophy. The eye muscles are rarely involved in St. Louis enceph-

litis, Australian X disease, Japanese type B encephalitis and lymphocytic choriomeningitis, although vision may be blurred in the latter. The optic muscles are nearly always involved in lethargic encephalitis, eventually always in tuberculous meningitis and at times in polioencephalomyelitis and syphilitic meningitis.

5. Spinal fluid observations: Any acute infection which causes a pyogenic response is ruled out if lymphocytes are found in the spinal fluid. When an abscess is deeply placed in the brain substance, the cellular reaction in the spinal fluid may first be lymphocytic, the type of cell changing to a polymorphonuclear leukocyte as the mass nears the brain surface. When there is an increase in the number of lymphocytes in the spinal fluid, the patient has some one of the encephalitis or tuberculous or syphilitic meningitis. If the spinal fluid contains 40 per cent or more of lymphocytes, the chances are that the true cellular response will eventually be a lymphocytic increase. During the first day or so after the onset of tuberculous meningitis, the cells found may be chiefly polymorphonuclear leukocytes. There is a change, however, within twenty-four

disease. There may be from a few to a few hundred cells in syphilitic meningitis.

The more protein present in the spinal fluid, the more severe the disease. Compared to the number of cells in lymphocytic choriomeningitis but little protein is found, and that is usually due to nucleoproteins, since filtering out the cells seems to remove it. A relatively small amount is present in lethargic encephalitis, definitely more in equine encephalomyelitis, Japanese type B encephalitis and St. Louis encephalitis, and a goodly quantity in tuberculous meningitis. In acute disseminated encephalomyelitis (and acute multiple sclerosis) there is nearly always a slight or a moderate amount of protein and few or, more often, no cells.

The spinal fluid Wassermann reaction will be positive in syphilitic meningitis and a syphilitic colloidal gold curve produced.

The sugar content is slightly increased in cases of epidemic encephalitis; it is definitely decreased in tuberculous meningitis.

6. Immunologic tests: There are only two ways to identify disease beyond a doubt: (1) by isolating the causative factor in the central nervous system and (2), if the patient recovers, by demonstrating that he has specific neutralizing antibodies in the blood serum. Isolation of the virus factor has occurred in lymphocytic choriomeningitis, St. Louis encephalitis, Japanese type B encephalitis, Australian X disease, equine encephalomyelitis and poliomyelitis. Specific neutralizing antibodies are present in the same diseases. No virus has ever been isolated in lethargic encephalitis, disseminated encephalomyelitis or acute multiple sclerosis.

CONCLUSIONS

If a patient has a disease of sudden onset and a spinal fluid containing but little protein and a great many cells, practically all of which are lymphocytes, and he begins to get well within a few days and there are no sequelae, the diagnosis may be lymphocytic choriomeningitis or abortive poliomyelitis.

If during the summer, in a community where horses, pigeons and other animals are dying of an epizootic disease, a patient develops a disease the onset of which is sudden and explosive in type, accompanied by high fever, not too obvious neurologic symptoms and from 200 to 2,000 cells, practically all polymorphonuclear leukocytes, and no organisms in the spinal fluid, the diagnosis is probably equine encephalomyelitis.

If during the summer a patient has signs similar to those of equine encephalomyelitis but with a lymphocytic count in the spinal fluid, then, dependent on the location, Japanese encephalitis, St. Louis encephalomyelitis or Australian X disease may be considered.

If the patient has a disease with a gradual onset, at first with little or no fever, and he slowly but inexorably becomes worse over a period of from seven to twenty-one days, the disease going on to a somnolent or encephalitic condition, at which time fever appears, and if at this time there are bizarre neurologic signs and an increase in the number of cells in the spinal fluid practically all of which are lymphocytes, the diagnosis is probably tuberculous meningitis. Guinea pig inoculations confirm this as well as demonstrating the presence of the organism.

If during the winter, fall or spring the disease starts suddenly with signs of an upper motor neuron lesion, such as a tic, nystagmus, double vision, absent abdomi-

TABLE 5.—Immunologic Data

Schilder's disease	—	—	—
Australian X disease	+	+	+
Acute disseminated encephalomyelitis and acute multiple sclerosis..	—	—	—

to forty-eight hours and the cells then become permanently and predominantly lymphocytes. The chances that a lumbar puncture would be done early enough in the disease to catch such a reaction are very slight and by the time the patient has reached the stage of somnolence the cells are practically always lymphocytic in type. The predominant cells in the first stages of equine encephalomyelitis and polioencephalomyelitis may also be polymorphonuclear leukocytes. In the latter instance, these change to lymphocytes within twenty-four to forty-eight hours. The change seems to occur so slowly, however, in equine encephalomyelitis that the patient may die before this happens. If the predominant cells are lymphocytes, as they usually are by the time the practitioner sees them, the patient has one of the diseases under discussion, Schilder's disease, acute multiple sclerosis and disseminated encephalomyelitis excepted.

The total number of cells in the spinal fluid varies. In lethargic encephalitis there may be no cells to a hundred, usually from thirty to fifty; in lymphocytic choriomeningitis, as in equine encephalomyelitis, Japanese type B encephalitis and Australian X disease, there may be as high as a few thousand. In tuberculous meningitis the cell count is low, the average being less than 100, although at times it may be as high as from 500 to 1,000. There is no cellular reaction in Schilder's

nal reflexes and hyperactive deep reflexes or even pathologic reflexes, and if the spinal fluid contains some protein and but a slightly increased number of cells, all of which are lymphocytes, the diagnosis is probably lethargic encephalitis.

If the disease starts slowly and extends slowly and the patient shows signs of disturbed vision, spastic paralysis and mental retardation, Schilder's disease should be considered.

If all the signs of an encephalitis appear and yet there are segmental palsies of a lower motor neuron type in the muscles of the arms or legs, the diagnosis is poliomyelitis.

If the patient develops spotty signs of motor and sensory involvement, especially a dissociated appreciation of pain and temperature sensation, and paralysis with bizarre reflex responses, and the spinal fluid contains few or no cells and an increased amount of protein, the patient probably has disseminated encephalomyelitis. Such a syndrome cannot be differentiated from acute multiple sclerosis at this stage. If the patient recovers and has recurrences, multiple sclerosis is thought of; if he remains permanently cured, disseminated encephalomyelitis is considered.

Clinical Notes, Suggestions and New Instruments

USE OF CELLOPHANE CYLINDERS FOR DESICCATING BLOOD PLASMA

A RAPID, ECONOMICAL AND BACTERIOLOGICALLY SAFE METHOD

F. W. HARTMAN, M.D., WITH THE ASSISTANCE OF
FRANK W. HARTMAN JR.
DETROIT

The present day use of blood banks and the tendency toward the use of stored blood and blood plasma have emphasized the importance of methods for preserving the plasma. At constant low temperatures liquid plasma may be stored safely for a number of months, but such conditions are difficult and expensive to maintain. Storage of large quantities of liquid under these exacting conditions is best accomplished only in stationary units, so that the mobility necessary for military or other emergency uses presents further expensive obstacles.

As pointed out by Flosdorf and Mudd¹ in 1935, the desiccation of serum was successfully accomplished by C. Martin in 1896, by M. J. Rosenau in 1895, by Noguchi in 1907 and by Burrows and Cohn in 1918. But all these methods produced physico-chemical changes in the material and a poorly soluble end product. Shackell in 1909 first introduced the process of desiccation by means of freezing, vacuum and sulfuric acid. Reichel in 1932 improved the method of Shackell and was able to desiccate large quantities rapidly but had difficulty in handling the hygroscopic product.

Flosdorf and Mudd introduced a modification of Shackell's and Reichel's method by processing the serum in the original containers. They (1) secured automatic regulation of the temperature during processing, (2) completed dehydration within a reasonable time, (3) provided a practical means of sealing the containers without loss of vacuum and (4) preserved asepsis throughout the process.

In 1938 Flosdorf and Mudd² further improved their method by the addition of a chemical desiccant—anhydrous calcium sulfate, or "drierite"—and designated it the "cryochem-process."

From the Department of Laboratories, Henry Ford Hospital.

2. Flosdorf, E. W., and Mudd, Stuart: An Improved Procedure and Apparatus for Preservation of Sera, Micro-Organisms and Other Substances—the Cryochem-Process, *J. Immunology* 31: 469-490 (June) 1938.

Again in 1940 a purely mechanical method of desiccation with a high vacuum or "desivac process" was described by the same authors.³

As early as 1917 Phillip A. Kober⁴ demonstrated the great speed with which water vapor passed through collodion bags and called the process pervaporation, at the same time describing the process of perstillation and percrystallization, which also utilized collodion bags.

Kunitz and Simms⁵ in 1928 and Simms⁶ in 1930 described a concentrating dialyzer which consisted of collodion sacs under partial vacuum, using it also to concentrate fluid to small amounts while keeping it at a low temperature.

Morell and Schwartzman⁷ in 1937 used small cellophane bags to prepare and preserve bacterial products.

William Thalheimer⁸ in 1938 pointed out that cellophane bags could readily be made from cellophane tubing and could be sterilized in steam. He found that bags containing 1,000 cc. of filtered serum could be reduced by from 20 to 25 cc. an hour if suspended at room temperature in front of an electric fan, and almost as fast in the refrigerator. Further, it was pointed out that the concentrated serum could be regenerated by placing the bag in water.

Following the introduction of cellophane tubing as a substitute for rubber tubing in intravenous therapy,⁹ we noted the rapid concentration of whole blood hung up in these three-eighths inch diameter tubes with complete desiccation of 150 cc. in twelve hours at 70 F. This led to a review of the literature and further experimentation with lengths of three-eighths inch tubing and with 4½ inch tubing. The initial loss of water vapor from blood plasma from the tubes was rapid, especially when a fan was played on them; but the further the concentration proceeded the slower the process proved, so that from seventy-two to ninety-six hours were required to desiccate 400 cc. of plasma completely. Further, it was noted that in the latter part of the process an abundant gray precipitate was thrown down. The final product was a rubbery opaque mass which was only slowly soluble after being ground in a mortar. Once this product was dissolved, it began precipitating out again so that it was not suitable for intravenous injections into either animals or man.

Flosdorf and Mudd emphasized the rapidity of desiccation and the porous product obtained by their method; efforts to approach their results led us to devise the double walled cellophane cylinders (E in the illustration), sealed at each end, thus increasing the surface area 100 per cent and allowing for the circulation of air through the center as well as about the outside. The inner cylinder is made somewhat longer, so that filtered air may be introduced with the plasma. The ends are sealed with heavily tinned screw clamps (B and C). A metal bar (D) is soldered across the outer clamp so that the cylinder may be attached to the rotating mechanism. F shows the rotating unit consisting of two wheels, each 24 or more inches in diameter, mounted on a steel axle. Rotation is accomplished at 20 revolutions per minute by means of a small geared motor. Circulation of warm dry air is provided by a 16 inch electric fan (H) on which are mounted several electric strip heaters (G). On the rotor, which measures 24 inches in diameter, from twelve to eighteen cylinder units (E) 14 inches long and 4½ inches in diameter, each containing 300 cc. of plasma, may be attached. Thus 5,400 cc. of plasma may be desiccated at one time with the smallest unit.

The cellophane cylinders of larger size were furnished through the courtesy of the Visking Corporation of Chicago. These cylinders are dry and are thinly coated with glycerin. In the

preparation of the cylinders they are washed in distilled water and then boiled in two changes of double distilled water for ten minutes. They are then again thoroughly rinsed with double distilled water. Now the sealing ring is applied at one end and double distilled water is run in to test for leaks. With the second sealing ring the cylinders are placed in a large Petri dish and sterilized with steam for twenty minutes at 30 pounds pressure. The cylinders must be kept moist throughout sterilization and until filled with plasma. Filling is done in a small closed room. The cylinders are separated with sterile forceps and the plasma is pipetted or poured between the inner and the outer cylinder. Then the edges are approximated and air filtered through cotton is introduced. The ends of the two cylinders are folded over twice and the sealing ring is put in place. The filled and sealed container is now attached to the rotor by means of heavy rubber bands.

As the rotation takes place the plasma comes in contact with the entire surface of the inner and outer cellophane cylinders, and mixing with the air produces marked foaming, which increases as the concentration of the plasma proceeds. As a result of the rotation and foaming the residue is desiccated as a light, airy froth which breaks up into porous flakes or crystals. The rate of desiccation of plasma ranged from 60 to 75 cc. an hour in the small cylinders (14 by 4½ inches) and from 130 to 160 cc. an hour in the larger cylinders (22 by 6½ inches).

After desiccation the froth is broken into flakes or crystals by gently working the cellophane cylinders between the fingers or hands. The cylinders are then folded and placed in flat tin boxes of appropriate size, sealed with "scotch" tape.

Apparatus used for desiccating blood plasma.

When the desiccated plasma is to be regenerated the cellophane cylinders are cut cleanly across with flame sterilized scissors or knife and the flakes are poured into the proper amount of sterile distilled water. From two to five minutes of shaking suffices to give a good solution which remains stable for a number of days at 4 C. The solution is usually a light amber and slightly opalescent. The solution is clearer after passage through a Mandler or Seitz filter, but this filtration is unnecessary. The regenerated plasma has been administered to a number of patients without reaction.

In case of an emergency in which distilled water is not available, the desiccated plasma may be regenerated by simply immersing the cylinders in water, as the cellophane is impermeable to bacteria and pyrogens. By rotation, sufficient water is taken up so that a satisfactory though concentrated plasma is obtained in a few hours.

Although the preservation of complement, prothrombin and the like is not considered essential in the desiccation of plasma for intravenous use, since these labile substances are lost for the most part during the storage of the whole blood, we are attempting to preserve these in the cellophane cylinder process by freezing the plasma in a thin layer between the two cylinders, from which the moisture is rapidly extracted without vacuum.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

INTRODUCTION

MORRIS FISHBEIN, M.D.

CHICAGO

More than fifteen years have passed since there appeared the first collection of articles on "Glandular Physiology and Therapy," published under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association. Our knowledge has advanced more in these fifteen years than in all the previous centuries of the life of man. So rapid has been the advance that it was necessary to revise the first series in 1927 and the second in 1935. With the passing of the third five-year period, the Council on Pharmacy and Chemistry has considered it desirable again to survey the advancement of our knowledge.

Conspicuous among the reasons for publishing a summary of endocrinology in 1924 was the existence of a pseudoscientific therapy based on glandular materials promoted by pharmaceutical manufacturers with but slight evidence as to actual utility. Much of this empirical and unwarranted therapeutics has disappeared. With the establishment of a new Food and Drug Law and with the coming of the new powers given to the Federal Trade Commission under the Wheeler-Lea Bill, it is likely that still further improvement will occur. The sale of extracts of tonsil, kidney, spleen and heart and, indeed, of mixtures of these with innumerable other preparations, is likely to be better controlled in the future than it has been in the past. No doubt obvious charlatanism will be controlled. However, the difficulty of evaluating therapeutic results and the great psychologic factor involved in most glandular disturbances combine to confuse considerably many physicians who, witnessing the marvels of scientific glandular therapy, are ready to accept as established claims for much that is in no way proved.

The entire volume published in 1927 included only 98 pages. The series issued in 1935 included thirty-one contributions and made a book of 528 pages. In the present series the number of manuscripts is not greatly increased but the amount of material is considerably larger. Particularly important are the articles concerned with the endocrinology of the female reproductive mechanism. Interesting also are those articles which discuss new aspects of our knowledge of the adrenal and the pituitary. Extraordinary advances have been made with reference to the antihormones. Of special importance also are those articles which discuss the interrelationships of various portions of the glandular

apparatus. The investigators who have contributed to this series of articles are all men of note in the fields about which they write.

When the publication of this series of articles in THE JOURNAL is completed, the material will again be made available in book form under the title "Glandular Physiology and Therapy."

RELATIONSHIP OF ANTERIOR LOBE OF THE HYPOPHYSIS TO OTHER ENDOCRINE GLANDS

PHILIP E. SMITH, PH.D.

NEW YORK

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

The laboratory and clinical research which has been carried on since the last edition (1935) of *Glandular Physiology and Therapy* has not revealed any essentially new interrelationships between the hypophysis and the other glands of internal secretion. Nor have investigations revealed that any of the interrelationships of the hypophysis given in the last edition were erroneous. Important investigations have been reported, however, during this period. Those in the field of carbohydrate and fat metabolism have been especially fruitful. Contributions of preceding years, among which those from the laboratory of Houssay are especially noteworthy, laid the basis for this subsequent extensive work, which has revealed the importance of the interrelationship between the hypophysis and the adrenal cortex in the metabolism of fats and carbohydrates. The results from the work in this field have not yet sufficiently matured to enable one to determine what practical value they will have in clinical medicine, but they contribute greatly to an understanding of the physiology of the hypophysis.

Some advance has been made in the purification of preparations containing the pituitary hormones, though the advances, owing to the protein nature of these hormones, have not kept pace with those made in investigations on the chemically more simple hormones (steroids) of the adrenal gland and the gonads.

Aside from the so-called metabolic principles, five hormones or principles continue to be generally recognized as issuing from the anterior lobe of the hypophysis. These are: (1) the growth (somatotrophic) principle; (2) the gonadotrophic hormone(s) or complex; (3) the thyrotrophic hormone; (4) the corticotrophic (adrenotrophic) hormone, and (5) the lactogenic hormone.¹ The evidence for the secretion of these separate factors is based on data secured from (1) the effects of hypophysectomy and (2) the effects of the injection of hypophysial extracts in (a) animals in which an endocrine deficiency has been established by the ablation of one of the endocrine glands, usually the hypophysis, and (b) normal animals.

From the Department of Anatomy, College of Physicians and Surgeons, Columbia University.

1. Other hormones from the hypophysis have been described, but their existence and action are not as well established as the existence and action of the five listed. These other tropic hormones are a medullotrophic (Collier) and a pancreatotrophic hormone (Anselmino, Harold and Hoffman).

EFFECTS OF HYPOPHYSECTOMY

The syndrome from a total deficiency of the anterior lobe of the hypophysis has been studied in all common laboratory animals, in monkeys and in man (Simmonds's disease). The studies are revealing in regard to the relationship of the hypophysis to the other glands of internal secretion and so merit a brief description.

The picture presented after hypophysectomy is quite uniform throughout all species of animals. The thyroid, the adrenal cortex and the gonads and accessory reproductive organs undergo profound involution, and their functional activity is greatly reduced. Parathyroid changes are less definite. Lactation ceases abruptly. The thymus involutes, although this may be an indirect effect. The capacity for muscular work is decreased, and activity is reduced: The appetite is diminished, hypoglycemia of varying degrees of severity develops, the circulation becomes sluggish, and the blood pressure is lowered. In young animals growth ceases abruptly, although very young rats may grow slightly. The viscera are small. Resistance to trauma and infection is greatly diminished, and the basal metabolism is lowered. The resultant effect, then, is atrophy or involution of most of the endocrine glands and polyglandular deficiency. Survival for extensive periods, however, is possible and is dependent to a considerable extent on maintaining the normal food intake and so preventing hypoglycemic coma or convulsions (especially in rabbits and monkeys) and on maintaining normal body temperature. Less care seems to be necessary with rats, ferrets and dogs in order to secure prolonged survival than with other species, including man. It is not probable that even with the greatest care any animal with complete ablation of the anterior lobe of the hypophysis will survive for a normal life span.

A small fragment of functioning gland is able, however, to maintain an animal in an apparently normal condition, and even a fragment of microscopic size has some effect.² In rats as little as 10 per cent of the gland will prevent the development of the disabilities, and in monkeys certainly not more than one fourth of the gland is necessary. The hypophysis thus has a great margin of safety, as is true for the other endocrine glands. A fragment which remains appears to have little or no capacity to regenerate, although with regard to this data on monkeys and man are not available.

Experimental work has not sufficed to elucidate the condition of hypofunction in a gland of normal size, for such a condition has not been reported to occur in animals and therefore cannot be studied in them. It is essentially a clinical problem, arising in certain cases from a preponderance of nonsecretory (chromophobe) cells at the expense of secretory (chromophil, i. e., acidophil and basophil) cells.

Experimentally it has been found that a genetic deficiency of one of the two secretory cell types of the anterior lobe of the hypophysis may exist. In the particular strain of mice in which this defect appeared, the acidophils were totally absent, but the chromophobes and basophils were present.³ The disabilities of hypophysectomy were all present except the atrophy of the genitals, thus supplying additional significant evidence that the basophils elaborate the gonadotrophic hormone

2. The literature is reviewed by Smith, P. E., in Allen, Edgar; Danforth, C. H., and Doisy, E. A.: *Sex and Internal Secretions*, ed. 2, Baltimore, Williams & Wilkins, 1939, p. 391.

complex. That a similar condition may occasionally exist in the human subject is indicated in a case recently reported by Shorr and co-workers.⁴ The opposite condition, overactivity of a cell type, has long been known from studies on acromegaly, in which there is a tumor of the acidophils.

Experimental and clinical work on the anterior lobe of the hypophysis thus shows that this gland influences, and in most cases directly controls, all of the other glands of internal secretion. These interrelations were all established at the time that the last edition of this book was published, and much of the work since then has been directed toward determining the number of hormones elaborated by the hypophysis and their action and toward the purification of preparations of these hormones.

ACTION OF PITUITARY HORMONES

The Growth Principle.—That the secretion of the hypophysis is essential for general body growth except in the earlier stages of development is unquestionable. The question of the existence of a specific growth-promoting principle would appear to have been raised largely for three reasons: 1. Preparations of the growth-promoting factor have not been free from substances affecting specific organs—thyroid glands, gonads and adrenal glands. 2. Growth is such a complex process, as has been especially pointed out by Stockard,⁵ that it is difficult to conceive of its being due to a single hormone. Each of the pituitary tropic hormones is essential for the growth of the specific organ which it affects. 3. The injection of prolactin—a lactogenic factor—causes growth in pigeons and dwarf mice, as shown by Riddle and collaborators.⁶ Moreover, in still lower forms (amphibian larvae) the hypophysis can be ablated without inhibiting growth to any great extent.

Specific endocrine stimuli, however, seem to be more necessary for the promotion of growth in mammals than in lower forms, and an interest in comparative physiology should not blind one to the fact that in medical practice the responses of mammals, especially those of man, are of predominant interest. In regard to the contamination of extracts of the growth factor with other anterior pituitary factors, it has been greatly reduced without impairing the growth-stimulating property of the extract.⁷ It thus appears, as stated by Evans nearly twenty years ago, that in mammals a specific principle is secreted by the hypophysis which is essential for general body growth. This principle appears to influence skeletal growth mainly by stimulating the epiphyseal cartilages, although the effect extends to the soft tissues and the viscera, also.

The Gonadotropic Complex.—The investigations reported by Cushing and collaborators and by Aschner on dogs some thirty years ago revealed that the gonads atrophied after hypophysectomy. Work in 1927 in which atrophic gonads of hypophysectomized rats were repaired and immature ovaries were stimulated to precocious development by administration of pituitary

extract gave conclusive proof that there was a factor (or factors) secreted by the hypophysis which was necessary for the structural and functional maintenance of the gonads and through them of the accessory reproductive organs. It was soon discovered, however, that the injection of extracts of hypophyses from different species did not give equal quantitative responses of the different types of tissue composing the gonads. In fact, Evans and Long showed in 1922 that crude extracts of beef hypophyses caused the formation of large amounts of lutein tissue in the ovaries of normal mature rats but had no follicle-stimulating effect. When it was found that the hypophyses of other species—rats, horses, sheep, man—gave pronounced follicle-stimulating effects, indirect evidence was thus supplied that more than one gonadotropic hormone had been encountered.

Fractionation and purification of gonadotropic extracts were undertaken by several investigators (Fevold, Hisaw and Leonard,⁸ Wallen-Lawrence,⁹ Evans and associates¹⁰). The present consensus from the laboratories in which these studies are being made is that two gonadotropic principles are elaborated by the anterior lobe of the hypophysis. The determination of the number of gonadotropic hormones is not easy to make, however, and in my opinion has not been definitely made. The length of treatment, the rate of absorption, the dosage and the site of injection (subcutaneous or intraperitoneal) all influence the response. That the solution of the problem is difficult is attested by the fact that within a six year period investigators in one prominent laboratory have stated that there was only one, that there were four and later that there were two pituitary gonadotropic hormones. The two postulated hormones are usually designated as the follicle-stimulating and the luteinizing hormone. The second hormone is sometimes designated as the interstitial cell-stimulating hormone instead of the luteinizer.

The hypophysial luteinizing hormone is not identical with the gonadotropic principle of human pregnancy urine, which is sometimes designated as the luteinizing hormone.¹¹ Little is known of the chemical composition of the gonadotropic factors, a statement which is also true of the other hypophysial principles.

The Thyrotropic Hormone.—It has been known since the classic work of Rogowitsch in 1889 that the hypophysis is influenced by the thyroid. The determination of an effect of the hypophysis on the thyroid is much more recent. This effect was first demonstrated by hypophysectomy and the injection of hypophysial extracts in amphibia¹² and later in mammals.¹³ The

threshold of the stimulus of structural response differs greatly in different species, the thyroids of rats being unchanged in structure by high doses of pituitary thyrotropic extract, whereas the thyroids of guinea pigs and rabbits undergo profound changes even with low doses. The injection of the thyrotropic extract in responsive species results in most of the thyroid changes characteristic of exophthalmic goiter, i. e., increase in size of the thyroid, depletion of iodine, loss of colloid, and hyperplasia and hypertrophy of the cells, with the characteristic irregular type of follicles. The infiltration by lymphocytes and the increase in connective tissue characteristically present in hyperplasia of human thyroids are not present in the hyperplasia experimentally induced. The absence of these changes may be due to the shortness of the period of treatment.

The injection of thyrotropic extract causes also a rapid and marked rise in basal metabolism, although a rise in metabolic rate from pituitary extract has also been reported in thyroidectomized animals.¹⁴ The thyrotropic extract induces a hyperplastic response of thyroid tissue *in vitro*¹⁵ and also of transplanted thyroids;¹⁶ so it can act independently of any innervation. In man massive doses have been shown to be effective in cases in which hypothyroidism is due to underfunction of the pituitary and not to lack of responsiveness of the thyroid. The thyrotropic extract of pituitary may have a limited field of usefulness, in that its administration will give information as to whether or not hypothyroid states are due to lack of responsiveness of the thyroid to stimulation by the hypophysis. It seems improbable, however, that it can have any extensive clinical usefulness.

The Corticotropic Hormone.—A stimulating action of the anterior lobe of the hypophysis on the adrenal cortex was first shown in amphibia. Hypophysectomy caused profound atrophy of the cortical but not of the medullary component of the adrenal, an action which was confirmed in mammals some ten years later.¹⁷ The atrophy could be prevented or the involuted glands restored to a normal condition by the administration of anterior lobe. There has been much question as to whether or not this cortex-stimulating action of the hypophysis was due to a distinct hormone, but the evidence supplied by Collip and co-workers,¹⁸ Moon¹⁹ and others shows that it is distinct from the thyrotropic, growth-promoting lactogenic and other hypophysial hormones. It appears to have no action other than that of stimulating the cortex of the adrenal.

14. This effect is stated to be due to a specific metabolic principle and not to a tropic hormone (Collip). This principle is remarkably thermostable and is resistant to boiling in dilute acid and alkali and to peptic digestion. Its injection causes a sharp rise in the metabolic rate for only a few hours. Collip states that it probably has its origin in the pars intermedia but that it is not identical with the melanophore-expanding hormone.

The injection of a pituitary extract containing the corticotropic factor restores the adrenals after hypophysectomy. It partly restores the work capacity of hypophysectomized animals, although their work capacity still remains somewhat subnormal, as is the case also when cortical extracts are administered.²⁰

The injection of cortical extract has been shown to repress the liberation of corticotropic hormone from the hypophysis.²¹ It seems probable that the enlargement of the adrenals in normal animals under conditions of stress is due to liberation of unusual amounts of corticotropic hormone by the hypophysis.

As in the case of the thyrotropic extract, it is not probable that the corticotropic extract will prove of much clinical value.

The Lactogenic Hormone.—The pituitary lactogenic hormone (prolactin; galactin; mammatropin) is purely a secretagogue and does not cause development and growth of the mammary glands. It is the only pituitary hormone that has been secured in crystalline form,²² although the potency of the crystals does not exceed and even may not equal that of the amorphous powder.

The test used for determining lactogenic activity is the response of the crop gland of the pigeon. Riddle has shown that his special preparation, prolactin, has other effects in pigeons, stimulating general body growth and the gastrointestinal tract. These effects are not secured in mammals by the injection of prolactin. Prolactin also stimulates the basal metabolic rate of thyroidectomized pigeons.²³

The injection of prolactin gives but a temporary increase in milk production in cows,²⁴ and clinical studies show little or no response following its injection in man.²⁵

Relations of the Anterior Lobe of the Hypophysis to Carbohydrate and Fat Metabolism.—The interrelationships of the anterior lobe of the hypophysis and other internal secretory glands in carbohydrate and fat metabolism is a subject which is complex. The reported studies dealing with the injection of pituitary extracts concern themselves largely with "effects" produced by very crude extracts, for the principle or principles producing these effects are in most cases very labile and a degree of purification equal to that achieved with the other pituitary factors has not been obtained. These studies, particularly those of Long and Lukens, have shown an important interrelationship between the hypophysis and the adrenal cortex in carbohydrate metabolism.

Although this complex interrelationship will be discussed more fully in another section, it seems justifiable to discuss briefly some phases of it here. Certain important findings stand out in this work. These are: (1) the greatly increased sensitivity to insulin of hypophysectomized animals, first reported by Houssay and Magenta, in 1924, which was shown later to be due

to the loss of the anterior lobe only (Houssay and Potick²⁶); (2) the amelioration of experimentally induced diabetes by hypophysectomy, reported by Houssay and Biasotti²⁷ in 1930 and frequently referred to as "the Houssay phenomenon"; (3) the production of temporary diabetes by injection of anterior pituitary extracts²⁸ and the production of permanent diabetes by a relatively short course of injections of increasing doses of crude pituitary extracts prepared at low temperatures, reported by Young²⁹ (diabetogenic effect), in which there is an injury of the islands of Langerhans in the pancreas,³⁰ with reduction of the pancreatic content of insulin;³¹ (4) the amelioration by adrenalectomy of diabetes induced by pancreatectomy, reported by Long and Lukens,³² and (5) the reinstitution of the diabetic condition by the injection of massive doses of extract of adrenal cortex, reported by Lukens and Dohan.³³ The injection of pituitary extracts causes ketosis in fasting animals.³⁴ It also will inhibit the action of injected insulin (glycotropic action of Young³⁵) and will maintain the levels of muscle glycogen in fasting hypophysectomized animals (glyco-static effect³⁰). The rate of absorption of carbohydrates by the intestine, which is decreased by hypophysectomy, can be restored to normal by the administration of thyroid.³⁷

It is tempting to ascribe these various metabolic effects to separate hormones but, as emphasized by Long,³⁸ this is not justifiable with the evidence available.

For the maintenance of diabetes after pancreatectomy, the presence of the adrenal glands has been shown to be essential by Long and Lukens. The ablation of these glands ameliorates the diabetic condition, and although amounts of cortical extract sufficient to maintain the life and health of the experimental animal do not restore the diabetic condition, massive doses will cause recurrence.³⁹ It appears that the pituitary stimulation of the adrenals, mediated by the corticotrophic hormone, is thus essential for the maintenance of the diabetic condition in experimental animals. The opposite condition, hypo-

glycemia, characteristic of fasting hypophysectomized animals, appears to be attributable, at least in part, to the absence of the stimulating effect of the hypophysis on the adrenals.

Ketosis from the injection of pituitary extract is also dependent on the presence of the adrenals, for this condition is diminished by adrenalectomy.³⁸ The inhibiting effect of injected pituitary extract on injected insulin (glycotropic action) and the maintenance of muscle glycogen in fasting hypophysectomized animals by the injection of pituitary extract appear to be direct effects, not involving the adrenals.³⁸

The inactivation of the thyroid induced by hypophysectomy apparently explains the decreased rate of carbohydrate absorption of pituitaryless animals. Althausen⁴⁰ showed that the injection of thyroxine increases the rate of absorption of sugars by the intestine in normal rats, and Russell,³⁷ following this lead, was able to show that thyroxine restored the normal rate of carbohydrate absorption in hypophysectomized rats. The dose necessary was less than that required for the restoration of the metabolic rate. It thus seems justified to refer the decrease in the rate of absorption of sugars after hypophysectomy to the loss of the thyrotrophic hormone and the consequent inactivation of the thyroid.

The observations made in experimental work on the role of the anterior lobe of the pituitary and the inter-relationship to other internal secretory glands in carbohydrate and fat metabolism, although of potential importance in medical practice, are not for the most part clinically applicable at present. An exception can perhaps be made with regard to the results of this work relating to the genesis of diabetes mellitus. Although it is generally recognized that many persons with diabetes do not show the islet lesions and thus differ from dogs made permanently diabetic by the injection of pituitary extracts, nevertheless, in other diabetic persons such lesions are present, and it seems not unreasonable to believe that overactivity of the hypophysis was a factor in causing this injury of the islets. As shown by White⁴¹ and others, the incidence of diabetes is higher in children who are unusually tall for their age than it is in those whose growth has not been so rapid, an observation which suggests that increased activity of the hypophysis may be associated with the juvenile onset of this disease. It is also reasonable to assume that there are variations in the susceptibility of the pancreatic islets of different persons to injury. Permanent diabetes does not develop in all dogs from the injection of diabetogenic pituitary extract, and in other species (rats, cats) no injury to the islets results from the injection of such a pituitary extract unless part of the pancreas has been removed.

RECIPROCAL ACTION OF INTERNAL SECRETIONS ON THE HYPOPHYSIS

The functional activity of the hypophysis, i. e., the rate of formation and release of the various pituitary hormones, is influenced by the secretion of the other endocrine glands, so that a balance exists between the various glands. This balance is also influenced by the activity of the other tissues and organs of the body and provides a mechanism which is responsive to the needs of the body. Some examples of the response of

the endocrine glands to environmental conditions are the hypertrophy of the adrenal cortex under conditions of stress (cold, toxins, and so on), the hyperplasia of the thyroid of the animal kept in a cold environment, and the enlargement and activation of the gonads in some birds and some mammals, which have a seasonal breeding period, with increased light.⁴² Some of the responses, at least, are due to increased activity of the hypophysis. Activation and enlargement of the gonads can be induced in the winter season and in some immature animals by increased illumination. After removal of the eyes, gonad activation can be induced in some birds by direct illumination of the hypophysis through a tube leading to that gland.⁴³

Adrenal and Hypophysis.—In a series of papers Ingle²¹ has shown that the injection of an extract of adrenal cortex causes a regression of the adrenal cortex which is nearly equal to that resulting from hypophysectomy and that this regression is due to a decrease in the output of corticotrophic hormone by the pituitary, for the injection of a corticotrophic extract of the pituitary prevented the cortical atrophy. It has been mentioned that the adrenal cortex atrophies after hypophysectomy. In intact animals the cortex hypertrophies under conditions of stress, but in hypophysectomized animals this hypertrophy does not take place. If placed in the cold, the animals thus operated on will succumb at temperatures which will be survived by normal animals or by hypophysectomized animals given an extract of adrenal cortex. Although it cannot be assumed that the adrenal glands are alone responsible for survival with noxious stimuli or under conditions of increased stress, nevertheless they are an important factor in the resistance and survival. The immediate stimulus causing the hypertrophy is the corticotrophic secretion of the hypophysis.

Gonads and Hypophysis.—The mechanism operating between the gonads and the hypophysis is similar to that described for the adrenals and the hypophysis. Both clinical and experimental studies show this interrelationship. The fact that the pituitary gonadotropic substance is excreted in man in the urine has given an unexcelled opportunity to study the factors which influence its secretion. The output of gonadotropin in the urine increases in amount if the gonads are removed or undergo involution, as at the menopause. As has been extensively shown by clinical studies, the administration of gonadal products, especially the estrogens, represses this enhanced output. In experimental animals the removal of the gonads results in increased potency of the pituitary, with an increase in the number of basophils. These structural changes can be prevented or the normal structure restored by the injection of estrogen or androgen.

Thyroid and Hypophysis.—Although a structural alteration of the hypophysis from the extirpation of an endocrine gland was first noted from thyroidectomy, and the administration of thyroid alters the proportion and structure of certain of the cell types of the hypophysis, nevertheless a demonstration of the influence of thyroxine on the functional activity of the hypophysis as complete as that in the case of the gonads and adrenals has not been given. The evidence, however, indicates that the output of thyrotrophic hormone

is repressed by unusual amounts of thyroid secretion. The administration of thyroid causes an involution of this gland, an effect which by analogy with relationships already discussed is presumably due to a decreased output of thyrotrophic hormone. Attempts to assay the urinary excretion of the thyrotrophic substance have given conflicting results.

In the preceding discussion it has been shown that excessive amounts of the secretion of the gonads, of the cortex of the adrenal and probably also of the thyroid inhibit the corresponding tropic hormones of the hypophysis, thus supplying an important mechanism for the maintenance of a balance between the hypophysis and each of these glands. There is also some evidence that an excessive amount of secretion of one of these glands influences the rate of secretion of the pituitary tropic hormones affecting other glands or structures. The administration of excessive amounts of estrogen promptly inhibits the growth of experimental animals and will inhibit the development of the mammary glands. The administration of thyroid increases the gonadotropic potency of the hypophysis, although the opposite condition, thyroid deficiency, does not reduce the pituitary content of gonad-stimulating hormone. The inhibiting effect of thyroidectomy on growth can be prevented by administering a hypophysial extract containing the growth-promoting factor, so that the inhibition probably is due, in part, to decreased secretion of this growth hormone.

RESPONSIVITY OF ENDOCRINE ORGANS AND OTHER TISSUES TO ENDOCRINE PRODUCTS

It is a fundamental tenet of the concept of internal secretion that the endocrine organs secrete chemical hormones ("messengers") which have specific effects, whether their action is on other endocrine organs, on a tissue group or on all the tissues of the body. This concept, however, does not justify the assumption that a hormone will induce its characteristic effect in all cases. In other words, a capacity of the end organ to respond to a hormone is also essential. Of the many examples which show this, two only will be given. Growth depends not only on the presence of the growth factor but on the responsivity of tissue, as is well shown by results obtained from injections of an extract containing the growth-promoting factor in two races of dogs—dachshund and collie. The injections in the former stimulate primarily a growth in the length of the vertebral column; the injections in the latter, an increase in the length of the legs.⁴⁴ There seems to be an inherent, hereditary capacity of response in the vertebral and appendicular components of the skeleton, respectively, in these two strains of dogs. The importance of the growth responsivity of various structures of the body has also been shown by breeding experiments in dogs. Experimental work on the gonads shows that at early ages some of the components of these glands are unresponsive to gonadotropic hormones; responsivity develops with aging. Although the gonadotropic hormones are essential to sexual maturation, it would not be justifiable to attribute sexual maturity solely to the onset of the secretion of these hormones; the development of responsivity to these hormones is also an essential factor. The responsivity of the end organ thus plays an important part in the action and the interrelations of the endocrine glands.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

DANGERS INCIDENT TO THE INDISCRIMINATE USE OF RADIUM COMPOUNDS OR RADON

IN THE TREATMENT OF CUTANEOUS DISEASES

ANTHONY C. CIPOLLARO, M.D.

NEW YORK

Radium from abroad has found anxious and eager buyers in this country during the past decade. Nine tenths of the radium mined each year finds a use in medicine.¹ The United States is probably the largest consumer of radium and radon for medical purposes, and the decreased cost resulting from a greater supply has made them available for wider distribution.

Formerly American dermatologists received but little instruction in the physical and chemical properties and the uses of radium. With each successive year there has been increased knowledge of the clinical applications of radium and radon. The modern dermatologist utilizes radioactive elements more efficiently than his predecessors and with discriminating judgment.

Notwithstanding increased knowledge, it is regrettable that some physicians, including dermatologists, use radium or radon for the treatment of various dermatoses without having had adequate training of either the disease under treatment or the agent. Some have the fallacious idea that the details of treatment of a lesion requiring irradiation can be obtained from a physicist. Proper treatment of a lesion, no matter how trivial, with an agent so potent as radium or radon requires exact diagnosis and judgment for the selection of the correct dose and technic applicable to the disease. This, of course, means specialized training and knowledge of general dermatology and of that specialized phase of radiology which pertains to dermatology.

The indiscriminate use of radium or radon by an unqualified physician is to be condemned. However, the responsibility also rests with those who sell or rent radium or radon, especially if the medical and physical experts of the distributors give diagnostic aid and suggest treatment without seeing the patient. It is the practice of a few physicians to make a snap diagnosis of a lesion without microscopic confirmation and then seek advice from the radium distributor regarding the dosage, filtration and other technical details. The advice is often given by a physicist or a company physician by mail or over the telephone. Obviously such practice leads to many undesirable results and needless suffering. Because the proper administration of radium treatments requires specialized knowledge, such treatments should be given only by experts who possess complete knowledge of the disease and also of the chemical and physical properties of the therapeutic agent, including dosage measurements. Henry K. Taylor,² chairman of the Special Committee on Radiology of the Medical Society of the County of New York, recently stated: "The

attention of the committee was called to two radium concerns selling their product by mail with instructions for use. The instructions accompanying the radium were issued by doctors who did not have the privilege of examining the patient. This practice is considered unethical." Other physicians and radiologists have had similar experiences.

It is alleged by some that the curtailment of the widespread distribution and use of radium or radon may deny to some the use of this valuable agent. In my opinion this allegation is not true when it is considered that radium or radon when improperly used can cause damage to the tissues and to the patient that may prove to be far more serious than the original condition. In fact, overtreatment with radium or radon can lead to cancer formation. There are many cases of lupus erythematosus, lupus vulgaris, verruca vulgaris, basal cell epithelioma, naevus vasculosus (port wine marks), psoriasis and sycosis vulgaris in which squamous cell epithelioma developed in active lesions of these diseases or in scars following the involution of these lesions as a result of overtreatment with or indiscriminate use of radium or radon. Therefore, unless radiation is properly used in diseases in which this agent is indicated, it is better not to use it. The mere availability of radium or radon does not compensate for the disastrous results following improper use.

Radium and radon should not be rented or sold to persons who are not qualified to use them, because this practice encourages diagnosis and treatment by mail or telephone by an individual who possesses radium or by a corporation engaged in the sale and rental of radium. There is no way that I know of to stop this practice. However, the dangers following the indiscriminate use of radium or radon can be brought to the attention of the practicing physician. Some steps should be taken toward ending the practice of distributors of radioactive substances giving technical information through a salaried physician or physicist who never sees the patient.

The Council on Physical Therapy desires to acquaint all physicians with the undesirable effects observed when radium and radon are used indiscriminately. This article deals only with the dangers resulting from the improper use of radioactive agents in treating diseases of the skin. The errors usually result from incorrect technic, poor judgment or ignorance.

The dermatologist of today is not the externist he was twenty years ago. He knows much more about the causation and management of many dermatoses. The training in the fundamentals of general medicine and in dermatology in particular is much superior to what it was formerly. Eczema, for example, is divided into several varieties. Identification of the particular variety gives clues as to the cause, proper investigation and therapy. In the case of eczema as in other diseases, irradiation with x-rays or radium was used to relieve symptoms and as a cloak to hide inexact diagnosis, lack of therapeutic resourcefulness, ability and knowledge. Now radiation therapy is used less often because of increased knowledge of the dermatoses. In fact, proper topical therapy, hospitalization, controlled environment and so on will usually produce quicker relief than will x-ray or radium therapy.

The improper treatment of certain diseases with radium, radon or x-rays often leads to irreparable damage to the tissues irradiated. Some of these diseases will be discussed.

Dr. George M. MacKee assisted in the preparation of this paper and gave many valuable suggestions.

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

CUTANEOUS NEOPLASMS

The physician who treats cutaneous malignant growths should be able to use expertly all the recognized methods of therapy. He should not depend on surgery or irradiation alone. He should be able to use with equal expertness scalpel surgery, electrosurgery, x-rays, radium and radon. The best method or combination of methods should be used for the presenting lesion. The dose of radon, radium or x-rays, the filtration, the distance, the overlapping, the time and other elements should be expertly judged in relation to the size and depth of the lesion, the location, the sex, age and physical condition of the patient and the degree of malignancy. The use of poor judgment in the selection of the proper method of treatment leads to bad results, complications and even death. At this point, I would like to cite an actual case that came to my attention several years ago. An elderly man was treated for a small epithelioma involving the ear with medium voltage and moderately filtered x-rays. It did not respond to the treatment administered and further treatment with x-rays was given. Only a portion of the lesion healed. The remainder was treated with radium. Several months later the lesion had spread and the cartilage and periosteum had been damaged. In addition there were evidences of an acute radiodermatitis. The resistance of the tissues was so lowered that there was also a superimposed eczematous process. Because of this secondary inflammation of the skin, it was impossible to ascertain easily what was dermatitis and what was epithelioma. The pain was so intense that narcotics had to be used for its relief. After the application of soothing remedies, the inflammation subsided. The epithelioma had spread all over the ear, including the external auditory canal and the underlying cartilaginous and bony structures. Extensive surgery was required to ameliorate the condition and reduce the pain. Several years of suffering and convalescence would have been avoided if this patient had been seen by a physician acquainted with all therapeutic methods for such lesions. He would have used a local anesthetic and would have destroyed the entire lesion with electrosurgery or scalpel surgery with plastic repair if necessary. Many other examples of poor results following the improper treatment of cutaneous malignant growths can be cited, but this one case suffices to illustrate the importance of selecting the correct method or combination of methods for the treatment of cancer of the skin.

NEVI

The cavernous and superficial (strawberry) angiomas occurring in children under 1 year of age usually respond well to irradiation. Treatment that may leave x-ray or radium sequelae is contraindicated because many of these lesions may disappear spontaneously. Port wine marks do not respond to irradiation. In fact, many cases which have been treated in the past with radium or radon now show varying degrees of radiodermatitis. No technic now known is safe for the treatment of these lesions. Hairy and nonhairy moles and lymphangiomas respond poorly when treated with radium, radon or x-rays. In fact, any degree of improvement of these lesions is accompanied by a corresponding degree of radiodermatitis.

HYPERTRICHOSIS, HYPERHIDROSIS AND SEBORRHEA

Hundreds of cases of radiodermatitis have been caused by treating hypertrichosis with x-rays and radium. Only a few years ago many beauty parlors were administering x-rays for the treatment of unwanted

hairs on any part of the body. In fact, "chain stores" were established throughout the country to administer the so-called Tricho treatment. Many cases of radiodermatitis resulted from the administration of x-rays by untrained lay operators. Fortunately the "Tricho Institute" no longer exists and American women are now sufficiently educated to avoid x-rays or radium for the treatment of superfluous hair. Irradiation is contraindicated for the treatment of this condition regardless of the technic employed and who employs it. Up to the present writing there is no safe radium or x-ray technic for the permanent removal of unwanted hair. Hyperhidrosis and seborrhea may be benefited by irradiation. No more than a safe amount should be given even though there is failure to cure completely. Much harm results in attempting to cure stubborn cases with x-rays or radium when they fail to respond to a safe dose. Attempting to inhibit permanently all secretory activity of the sweat and sebaceous apparatus with radioactive agents may lead to permanent and harmful changes in the surrounding cutaneous structures.

MYCOSIS FUNGOIDES

Mycosis fungoides, a serious disease of the hemopoietic system which often ends fatally, responds exceedingly well to irradiation. As a rule small doses of x-rays or radium administered at weekly intervals to the affected areas causes the lesions to respond. However, when overtreated there may result serious sequelae affecting the skin as well as the blood forming apparatus. Judicious use of the radioactive agents may keep patients with mycosis fungoides free from lesions for many years and may prolong life indefinitely. In fact, many patients with mycosis fungoides die of other diseases. The fungating and ulcerative stage of this disease is seen infrequently now. This is due to the fact that irradiation with x-rays, radium or radon often controls the disease. In the light of our present knowledge it is a mistake to irradiate the bones, spleen and gland bearing areas with large doses of heavily filtered and high voltage x-rays. The disease affects the skin. Radiation applied directly to the affected skin areas in small doses and whenever indicated is all that is required to cause involution of the presenting lesions and to prevent the formation of the fungating and ulcerative lesions.

KELOIDS

Keloids and other benign new growths and hypertrophies and inflammatory dermatoses such as psoriasis or eczema should not be treated with an amount of radiation sufficient to produce erythema, because even one occurrence of a mild erythema may eventuate in disfiguring and even serious sequelae. Failure to cure a benign condition is not so serious as the harmful results which follow the injudicious use of radiation. Keloids are often only of cosmetic importance. Many lesions are radioresistant, especially the older ones. Therefore forcing the issue with x-rays or radium should be avoided. Overdosage may not only fail to improve the condition but may also lead to irreparable skin damage and even to a neoplasm.

Many other diseases might be discussed in detail, but a sufficient number have been mentioned to demonstrate that overtreatment of dermatologic conditions with radiation leads to disastrous consequences.

Radiation therapy is used with more discrimination by the well trained modern dermatologist. The physician who is not a dermatologist is apt to use radium or x-rays when there are better methods. He is apt

to administer a dose which is too large or he may give too many treatments or the intervals between treatments may be too short. In the presence of congestion caused by the disease or inflammation caused by topical remedies (counterirritant ointments or lotions or strong ultraviolet rays) the biologic effect of the radiation is greater than is anticipated. Such congestion or inflammation may mask a slight acute radiodermatitis with resulting unexpected radiation sequelae. Errors are also made in forcing the issue with radiation therapy: If certain cases of eczema, psoriasis and other dermatoses do not respond to an adequate amount of radiation, the continuance of such treatment may lead to therapeutic fastness or radiodermatitis.

Many cases of radiodermatitis and other undesirable radiation reactions result from the improper protection of normal tissue from scattered and secondary radiations. Such areas as the hairy parts, eyes or testes should be protected with suitable opaque materials in all instances. Overdosage may result from crossfiring, back scattering and overlapping of rays. The inadvertent omission of the filter or the improper selection of the filter when administering a radium or x-ray treatment accounts for some cases of radiation sequelae. Radiodermatitis may also result from haphazard guesswork in dosage determination, from faulty diagnosis, from repeated treatment of recurrences and from failure to obtain a history of previous treatments with radium or x-rays. The application of radium or radon over an area that was previously repeatedly examined with x-rays or by fluoroscopy may lead to a radiodermatitis. Perhaps the greatest harm is done with radium by using it when not indicated or as an unnecessary aid to other treatment.

A physician who uses x-rays or radium for treating dermatologic conditions should be a dermatologist or should be guided by one. The necessity for this attitude is best illustrated as follows: A patient may complain of anal pruritus. The diagnosis of essential pruritus ani should be confirmed. Such possible causes as a fungus, diabetes, intestinal parasites, anorectal disorder, allergic conditions or neurodermatitis should be eliminated. If it is assumed that the condition is essential pruritus ani and an adequate amount of irradiation fails to relieve it, then it is unlikely that additional treatment will be effective. The indications, the contraindications, the response of certain diseases to a given quantity of radiation, the tissue response and the natural evolution and involution of dermatoses are best understood by dermatologists. It is also important that the dermatologist who uses radiation be thoroughly familiar with all phases of radiation that apply to the treatment of cutaneous diseases. The details of acute and chronic radiodermatitis may be found in standard textbooks.³

I hope that it has been sufficiently emphasized that the proper administration of radium, radon or x-rays in the treatment of cutaneous diseases requires specialized training in both dermatology and radiology. Also that company physicists are not qualified to advise dermatologists or radiologists in the proper use of radium. Especially is it poor practice to obtain advice from company physicians and physicists regarding technic, filtration, dosage, method of administration of radium or radon without the consulting physician or physicist seeing the patient. The practice of telephone and mail consultation is particularly undesirable.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

THE PRESENT STATUS OF THE GONADOTROPIC HORMONE FROM THE SERUM OF PREGNANT MARES: GONADOGEN (THE UPJOHN COMPANY), ANTERON (SCHERING CORPORATION) AND GONADIN (CUTTER LABORATORIES) NOT ACCEPTABLE FOR N. N. R.

The gonadotropin obtained from the serum of pregnant mares is being actively marketed at the present time for therapeutic purposes. The Upjohn Company claims that its preparation of pregnant mares' serum (Gonadogen) is useful in males with hypogonadism of pituitary origin, in oligospermia and sterility, and in females for menstrual irregularities, functional bleeding, certain types of dysmenorrhea, sterility and failure of ovulation.

Schering Corporation recommends Anteron, a similar preparation, in the treatment of amenorrhea, functional bleeding and hypogonadal sterility in females, and sterility and hypogonadism in males.

Gonadin is advertised by Cutter Laboratories to be indicated in amenorrhea, functional bleeding, sterility in the female and disorders of sperm formation in the male.

On theoretical grounds, gonadotropic hormone from serum of pregnant mares appears to possess several desirable physiologic properties which might be enlisted for therapeutic purposes:

1. It is capable of inducing ovarian growth in primates, in contrast to chorionic gonadotropin (from human pregnancy urine), which is unable to affect such ovaries in this regard.
2. It stimulates the germinative epithelium of the ovaries and testes in laboratory animals.
3. Its physiologic properties resemble those of the anterior lobe gonadotropic factors.
4. It can be prepared for commercial purposes in a more concentrated and purer form than gonadotropic extracts of the anterior lobe.

It has been fairly well demonstrated that mare serum gonadotropin is effective in inducing some degree of ovarian growth in human beings. Westman¹ reported that seven women responded with an increased growth of the follicular apparatus, which in five cases he considered excessive. Moricard and Saulnier² likewise stimulated follicular development with a similar preparation in several women.

In 1938 Davis and Koff³ reported that they had induced ovulation in women with the mare serum gonadotropin administered intravenously. No one, up to this time, had succeeded in producing this reaction. The work of these investigators aroused great interest in this preparation, and the application of such therapy to certain gynecologic disorders was held most promising. These authors recognized the possibility, however, that ovulation might be induced in this manner only in women with normal ovaries, which would, of course, limit its therapeutic application. Up to the present time the work of Davis and Koff has been confirmed only by Siegler and Fein.⁴ On the other hand Hartman,⁵ working with a large number of monkeys, could induce only infrequent ovulations by mare serum gonadotropin injections (7 per cent of 104 animals). He observed varying degrees of ovarian stimulation in most of his animals, but a considerable number remained refractory. The

5. Hartman, C. G.: The Use of Gonadotropic Hormones in Adult Rhesus Monkey, *Bull. Johns Hopkins Hosp.* **63**: 351 (Dec.) 1938.

stimulation consisted chiefly of follicular enlargement and only an occasional corpus luteum.

Among the conditions which appeared, on theoretical grounds, to be suited to therapy with this form of gonadotropin were those in which there was a failure of ovulation. Certain cases of amenorrhea, oligomenorrhea and menorrhagia are included in this category. Functional sterility in some patients is also supposed to result from a defective ovulation mechanism. Successful treatment of the latter condition would, of course, be a great boon to these childless couples. Whether or not the ovum from such an artificially induced ovulation would be normal at all times remains to be demonstrated. Other suggested indications are menstrual dysfunctions due to abnormal follicular development and some types of testicular dysfunction, including defective sperm formation.

The reports on the clinical trials with this substance have been, unfortunately, rather unsatisfactory to date. Bowes⁶ reported satisfactory results in regulating the menses in four out of five patients. Kennedy and Shelton⁷ have likewise reported beneficial responses in three cases of menorrhagia and eleven cases of amenorrhea. The data in these reports were clinical only. The recent report of Hall⁸ disclosed extraordinary results in a large group of patients (135). Eight of seventeen patients with genital hypoplasia were reported "cured," twenty-four of forty-three sterile women became pregnant, and 57.6 per cent of those with menstrual disturbances were also "cured." This work requires confirmation, since no other investigators have approached the success of Hall and since no objective evidence was presented by this investigator. Severinghaus and his associates⁹ have used gonadotropic hormone from serum of mares in both males and females with encouraging results.

The investigations of Gray¹⁰ are the first to include laboratory data which demonstrate the effect of the mare gonadotropic substance on the reproductive tract of women with menstrual disturbances. This worker at intervals took biopsies of the endometrium of his patients before and after therapy was instituted. In four of eleven cases of secondary amenorrhea the endometrium was changed to the secretory type after two to thirteen months of treatment. Eight of the eleven patients responded with regular menstruation or "fairly so." In seven cases of menorrhagia with endometrial hyperplasia bleeding was unchecked after one to sixteen months of treatment, and there was little effect on the endometrium. In seven cases of metrorrhagia, two responded with regular menstruation. The others were not significantly affected, and only one endometrium was altered to the premenstrual type. In six patients with "minor metrorrhagia" there was improvement in only one.

Gray questioned Hall's results in treating functionally sterile women: "One is led to presume that 55 per cent [twenty-four of forty-three] of cases with sterility, at least in that series, were due to failure of ovulation. In our opinion sterility due to failure of ovulation in a woman with normal, regular menstrual periods is a distinct rarity."

In the male, Kunstadter¹¹ has reported satisfactory results in cryptorchism and hypogonitism in boys treated with mare gonadotropin, but there appears to be, from his results, no advantage for this therapy over that with chorionic gonadotropin. Recently Rowlands and Spence¹² have shown that mare serum gonadotropin was rather unsatisfactory in the treatment of cryptorchism. Furthermore, a state of refractoriness was induced when this substance was administered for several weeks, which appeared to be due to the development of an antigonado-

tropic substance. No competent studies on the treatment of other disorders of the male gonads (including sterility) with mare gonadotropin are available to date.

The evidence in the literature, which forms the basis of this report, except for several lesser references, is definitely inadequate as a basis for the recommendation of therapy with mare gonadotropin. Our knowledge of the physiologic and pathologic action in primates, especially man, is still most uncertain. Certainly there is little justification for claims of consistent therapeutic success in gonadal disorders on the basis of the physiologic reactions obtained in laboratory animals and the meager clinical data reported up to the present time. It is apparent that adequate investigations from the laboratory standpoint, which should include endometrial biopsies, hormonal assays, vaginal smears and chemical studies, are essential for the proper evaluation of the effect of this gonadotropic substance on the abnormal as well as the normal human ovary, and secondarily on the accessory sex organs.

Further experimentation is obviously required under suitable conditions and by investigators whose special training qualifies them for the appropriate study of this material. Until the time when the status of gonadotropin from serum of pregnant mares may be properly evaluated, physicians are cautioned that the use of this substance is still in the early experimental stage, that the claims made by the manufacturers are without satisfactory foundation, and that additional publication of more satisfactory evidence is necessary before this substance should be used in routine practice.

The Council, therefore, voted that the preparations of gonadotropin from serum of pregnant mares marketed as Anteron (Schering Corporation), Gonadogen (the Upjohn Company) and Gonadin (Cutter Laboratories) be declared unacceptable for inclusion in N. N. R., since their advertising claims for its therapeutic use are based on an insufficient amount of scientific evidence and inadequate confirmation of reported results. The right, under the Council's rules, of any firm to the use of a proprietary name for this substance was not considered at this time.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ALLERGENIC EXTRACTS-MULFORD (See New and Nonofficial Remedies, 1940, p. 32).

The following additional products have been accepted; they are marketed in 5 cc. ampule vials:

Products marketed in dilutions representing 0.005 mg. of nitrogen per cubic centimeter:

*Rat Hair.*⁴

Products marketed in dilutions representing 0.05 mg. of nitrogen per cubic centimeter:

Allspice,¹ Aniseed,¹ Caraway Seed,¹ Cashew Nut,¹ Gelatin (Cattle),¹⁹ Hazelnut,¹ Hops,² Horse-Radish,² Mace,² Pimento,² Poppy Seed,¹ Sage,¹ Tapioca,¹ Thyme.¹

Products marketed in dilutions representing 0.25 mg. of nitrogen per cubic centimeter:

Curran,² Pigeon Feathers,⁴ Turkey Feathers.⁴

Products marketed in dilutions representing 0.5 mg. of nitrogen per cubic centimeter:

Anchorvy,² Butterfish,² Castor Bean,¹¹ Catfish,² Chickory,¹ Date,² Lime,² Pike,² Poroy,² Quince,² Sardine,² Weakfish,² Whitefish.³

Product marketed in a dilution representing 0.75 mg. of nitrogen per cubic centimeter:

Feathers Mixed (Chicken, Duck and Goose).⁴

Castor Bean, marked 11, is prepared for extraction as follows:

The material is ground and washed with toluene and ether until the washings are colorless. The residue is extracted with buffered salt solution for seventy-two hours at room temperature. The extract is boiled for three minutes and filtered through a Mandler candle.

MAGNESIUM TRISILICATE (See THE JOURNAL, April 6, 1940, 1355).

The following dosage form has been accepted:

Tablets Magnesium Trisilicate, 0.324 Gm. (5 Grains).
Prepared by the Smith-Dorsey Co., Lincoln, Neb.

SATURDAY, DECEMBER 7, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

LIFE-SAVING SERVICE WITHOUT RECOGNITION

The disaster to the U. S. S. *Squalus*, the submarine from which a considerable number of lives were salvaged, is no doubt still fresh in the minds of many American citizens. Few people realize, however, the part played by the Medical Corps of the United States Navy in the saving of life in this catastrophe. Early in June 1939 the submarine *Squalus* dived to the bottom and did not come up. Apparently water had rushed into the submarine, and twenty-six men who had been locked in the flooded compartments perished. In the forward compartments were thirty-three men who still lived. Twenty-four hours after the *Squalus* sank the Navy had its experts and rescue devices on the scene. Divers went down in a diving bell, slid a shackle over a ring on the deck of the submarine and attached a cable. Then the rescue bell was clamped over a hatch on the sunken ship, the hatch was opened, and one

officer and six seamen climbed into the bell and were raised to the surface. By this process, in a period of eight hours every living man aboard the *Squalus* was taken into the bell. Except for an accident which occurred on the final trip, all were released in that time. One officer and seven men were held in the bell by a jamming of the cable, which, however, was finally cut so that all were rescued.

The saving of the men on the *Squalus* was possible largely because of some extraordinary scientific investigations made by members of the United States Navy Medical Corps in the years since 1932. In those investigations Lieut. Albert R. Behnke contributed notably. A series of papers has been published in the *United States Naval Medical Bulletin*. These investigations, which are concerned with a determination of the cause of accidents with the submarine escape apparatus, the narcotic action of nitrogen, the development of the use of helium, improvements in decompression tables, the development of an effective method of utilizing oxygen in the treatment of air embolism and the discovery that the diffusion of helium through the skin may be used as a measure of peripheral circulation are all fundamental contributions, on which rescue work such as that involved in the saving of the men on the *Squalus* must be based.

Significantly, in all of these investigations, involving more than twenty-five individual contributions to scientific medical literature, the physicians have themselves submitted to various tests before any enlisted men were permitted to volunteer for such a purpose. The value of their work is shown by the fact that only two minor cases of bends developed out of 640 dives, whereas bends occurred almost daily in previous rescue work even though the depths were much less.

The story of the salvaging operations on the U. S. S. *Squalus* was published in the *United States Naval Medical Bulletin* for October 1939. The *Squalus* disaster provided a crucial test for the preparation which Navy medical officers had made over a long period of time. The medical discoveries already mentioned were supplemented by some engineering innovations involving the fabrication of fireproof, electrically heated garments for cold-water diving, improved recirculation of gas through the diver's helmet and the perfection of telephone communication. Indeed, these also were medical as well as engineering problems before they were finally perfected by the engineers. It was found that diving in semidarkness to a depth of 240 feet for the purpose of tunneling under the submarine and attaching the hoses was too dangerous when divers breathed air. The accumulation of carbon dioxide and nitrogen narcosis impaired neuromuscular coordination to such an extent that simple tasks could be carried out only with great difficulty. The substitution of helium for nitrogen in the air minimizes the narcotic symptoms associated with air breathing under pressure. Substitution of oxygen for air or a helium-oxygen mixture in the lungs allows

excess nitrogen or helium gas to diffuse from the body at a maximum pressure head.

The complete story of the *Squalus* disaster and the rescue has not yet, of course, been told. At this time, however, not one of the three medical officers in attendance on the *Squalus*, including Lieuts. Oscar D. Yarbrough, Albert R. Behnke and Thomas L. Willmon, has been given any special award in recognition of his performance. With the exception of two pharmacist's mates, none of the Hospital Corpsmen who worked in this disaster have been recognized by an award. Nevertheless, practically every other officer and Naval "rating" who took part in the salvage has apparently been given special recognition. The reticence of the medical profession in seeking rewards for such service is proverbial. In this instance, when the attention of all the world was focused on the plight of the men who sank in the *Squalus*, when it is recognized that only years of preliminary efforts on the part of medical investigators in the United States Navy made possible the salvaging of those who were saved, when it is recognized that these men in person and the Hospital Corpsmen who were associated with them were in attendance on the actual salvaging operation, neglect to give them the type of special award given to the nonmedical personnel is so evident as to demand this statement. Organizations which know how to impress their opinions on government officials might well adopt official actions to indicate their belief in the justice of the claims of these men to governmental recognition.

SELENIUM AND DIETARY PROTEIN

Within the past few years the etiology of "alkali disease," a condition affecting horses, cattle, swine and poultry of certain areas of South Dakota, Nebraska and Wyoming, has been elucidated.¹ Wheat, corn and barley grown on soils of these areas contain selenium, a chemical cousin of sulfur; this element is definitely associated with the protein fraction of "toxic" grain.² A preliminary report recently announced the actual isolation from seleniferous plant material of a crystalline organic compound containing selenium and having the properties of an amino acid.³ Selenium also occurs in body protein of animals fed for long periods on selenized grains.⁴ This selenium behaves in some respects like that found in proteins of selenized grain, and possibly the toxic element is present in a similar chemical combination in both cases.

As persons living in areas where "alkali" disease is endemic also ingest food containing selenium, it seemed possible that chronic selenium poisoning might also be

encountered in residents of these areas. Nevertheless, despite the fact that persons in selenium-endemic areas may consume this substance in food up to 0.2 mg. per kilogram of body weight daily, convincing evidence of serious chronic selenium poisoning from this source has never been reported in man.⁵ A possible explanation of this situation is afforded by the observation that in animals the toxicity of selenium which is chronically ingested in food is influenced greatly by dietary factors.⁶ It has been found, for instance, that an amount of selenium which will cause extensive tissue damage to animals on a diet low in protein and high in carbohydrate will do little or no harm to animals maintained on diets high in protein and low in carbohydrate. Moreover, not only the toxicity of naturally occurring food selenium but also the toxicity of sodium selenite is influenced by the amount of protein in the diet.⁶

Smith⁵ has pointed out that the toxicity of selenium in food seems to be determined within certain limits by the ratio of selenium to protein in the diet rather than by the level of selenium in the food as heretofore supposed. This aspect of the selenium problem has been confirmed and extended in a recent report by Gortner,⁶ who observed that the quality as well as the quantity of protein in seleniferous diets assumes a role in determining the toxicity of selenium. Casein and lactalbumin tend to counteract the toxicity of selenium, for instance, while edestin and gelatin are not effective in this respect. These recently discovered relationships between the toxicity of selenium in food and the quality and quantity of the protein in the diet have an important bearing on the question of selenium as a health hazard to man and they serve to emphasize once more the fundamental importance of good diets in the maintenance of public health.

Current Comment

TEACHING OF SOCIAL MEDICINE

According to a recent study "A total of 715 courses covering one or more topics on social medicine was offered by 139 colleges and universities."¹ In addition there were more than a thousand courses in which one or more lectures were devoted to some aspects of social medicine. The 715 full and part courses were analyzed as to the frequency of the topics included. Thus, 432 courses treated "social and economic problems affecting public and individual health," 295 dealt with "health insurance, general," 180 with "voluntary health insurance," and 37 with "compulsory health insurance." There were 112 full courses on social medicine given at sixty-three colleges and universities. These are scattered through a variety of departments, some of which would

seem to be scarcely related to the subject. Twenty courses are in the department of biologic sciences, thirty-eight in physical education and hygiene, twenty-seven in social work and thirteen in sociology. None of the courses were found in departments of economics and history. Comments would seem to indicate that the courses given in the departments of biologic sciences and physical education and hygiene place the emphasis on treatment of individual and social health rather than on broader questions of policy in the organization of medical services. The fact that 512 full or part courses deal with some phase of health insurance arouses curiosity as to the extent to which such courses are descriptive and analytic and how much of them are propaganda. The fact that little use has been made in any of these courses of the material on these subjects in the Bureau of Medical Economics of the American Medical Association may indicate that most of the information placed before students is derived by prejudiced instructors from private, foundational and governmental propaganda institutions and is largely colored by these sources.

THE POST HAS NEVER SEEN A VITAMIN!

An advertisement for the *Saturday Evening Post*, November 27, was headed "Two Things You Never Saw Photographed." More than half of the advertisement is a reproduction of an f:6.3 Eastman anastigmat lens, with the following text:

In a Dutch prison in Java over thirty years ago, a young medical officer noticed that prisoners eating polished rice were suffering. Then he made the discovery that the trouble was caused not by something *present* in the rice, but by something *absent*—something hidden in its silvery skin. Something we now call a vitamin.

Scientists have traced a dozen evils to missing vitamins—from beriberi to night blindness. They know that some foods are rich in vitamins. And some are not. But you never saw a *picture* of a vitamin, did you?

If the writers of the *Saturday Evening Post* advertisement had consulted the many vitamin research laboratories, both in the industry and in academic circles, they would have seen photographs aplenty of vitamins—not only of thiamine (in the form of thiamine hydrochloride), the lack of which causes beriberi, but pictures of crystals of vitamin A, of nicotinic acid, riboflavin (vitamin B₂), pantothenic acid, ascorbic acid (vitamin C), the crystalline vitamin D compounds and a number of others. They even used for the illustration a 6.3 lens, when amateur photographers would have known better. Perhaps this incident reflects what is wrong with much so-called scientific copy. The writers are more interested in the "idea" than in scientific accuracy. They could have found, by a very small amount of research first, that many vitamins have been isolated in crystalline form; second, that there are many potent substances that have never been seen. There is the "something" that causes a cancer cell to assume malignancy; there are viruses of a number of serious diseases; there is the "something" that makes men go to war; and then finally there is the birth of an idea. These thoughts we present to the agency with no thought of further recompense than the joy of giving; and that cannot be measured either.

NATIONAL PHYSICIANS' COMMITTEE

Many inquiries have been received relative to a mailing which the National Physicians' Committee for the Extension of Medical Service has just sent, we are informed, to every physician in the United States. In this statement of its postelection position, policy and program, attention is called to the statements made by President Franklin D. Roosevelt and Mr. Wendell Willkie on the subject of socialized medicine previous to the election. The committee points out the importance of sustaining public opinion so that the public will come to understand the vital importance of maintaining the delicate and subtle relationship of doctor and patient and will support the independence of the medical profession. At a meeting of its Management Committee, held in Chicago on November 10, the National Physicians' Committee, says the statement, adopted the following resolutions:

Be it recorded that it is the unanimous opinion of the Management Committee of the National Physicians' Committee that under conditions now prevailing there is a greater and more pressing need than at any previous time for such activities as those of the National Physicians Committee.

Be it recorded as the unanimous opinion of the Management Committee that we continue the operations of the National Physicians Committee with increased vigor.

With this decision the National Physicians' Committee has sent to the medical profession a list of activities and objectives proposed for the coming year and a plan for sustaining the organization so that it will be able to function effectively. This statement follows:

NATURE OF ACTIVITIES AND OBJECTIVES

It is essential that funds be provided for:

1. A continuous flow of articles to more than eighty medical journals.
 2. Stimulating discussion of this all-important issue in forty-eight state medical meetings, in the meetings of two thousand county medical societies, and hundreds of sectional and special medical meetings and conferences.
 3. Preparing and providing for the preparation of articles and releases for thousands of newspapers and hundreds of magazines, and arranging for their publication.
 4. Speakers for medical and public meetings and arranging for physicians appearing before local groups and on local radio broadcasts.
 5. Radio broadcasts and the preparation of speeches and radio broadcasts to be generally available, and the providing of electrical transcriptions of short speeches and radio broadcasts and arranging for their effective use.
 6. The maintaining of strategically important public contacts.
 7. The arranging of conferences with boards of hospitals and clinics; business, industrial and other lay groups; and for group meetings of laymen.
- all to the end that:
- (a) political control of medicine can be avoided;
 - (b) the independence of the profession and the pattern of medical practice be preserved; and,
 - (c) the American people can be resold on the incomparable advantages of the American Way of Life.

The medical profession generally has been asked to contribute to a furtherance of these commendable objectives. The work of the National Physicians' Committee, which is wholly in charge of its own Board of Trustees, thus contemplates an expanded program of public enlightenment. Since new legislation in the field of medical service is constantly before Congress, an agency of this type will find a large field for its service.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

THE 1940-1941 MILITARY TRAINING PROGRAM

Participation of the Medical Department of the Army

Uppermost in the minds of all physicians at present is undoubtedly the question of national defense. The medical departments of the armed forces must plan to meet the immediate twofold problem of furnishing an adequate medical service to the men of our unprecedented peacetime Army and Navy, and of training the large number of Medical Department trainees who, at the expiration of their twelve months military service, will pass to the Enlisted Reserve Corps. They will furnish the trained personnel required for mobilization in the event of a national emergency. The Surgeon General of the Army has furnished the following outline regarding the participation of the Medical Department of the Army in the 1940-1941 military training program:

THE NEED FOR PERSONNEL

The total strength of the army of the United States next spring will be approximately 1,400,000. This represents a Regular Army of 400,000 officers and men, the National Guard of the several states federalized as the National Guard of the United States, numbering 200,000, and citizens selected for military training during the coming twelve months—about 800,000 in number. The latter will receive their training in active units of the Regular Army and of the National Guard, in Regular Army inactive units activated for training purposes, in the numerous installations required for the overhead of these forces and in enlisted replacement centers throughout the nine corps areas of the country.

PROVISION OF HOSPITAL BEDS

The Medical Department is charged with providing adequate medical service for the entire army of the United States at posts, camps and stations within and beyond the continental limits of the United States. In each military station in the United States there will be a hospital with four beds for each hundred of the military population. The operating room, kitchen, messing facilities and clinics in each of these hospitals will be of sufficient size to provide service for an additional patient per hundred men so that in an emergency it will be necessary to construct only the additional ward buildings. Furthermore, there will be general hospitals suitably located throughout the United States to provide an additional bed per hundred of the military population.

The provision of 5 per cent of hospital beds which can be rapidly expanded to 6 per cent may appear excessive when compared with hospitalization provided for the civilian population of this country. However, all of the military sick, including such cases as in civilian life are ordinarily cared for in their homes, must be treated in hospitals, since they cannot receive satisfactory care in the barracks. In addition, when young adults are brought together in large groups, contagious and infectious diseases that spread rapidly under such conditions occur much more frequently than in civil life. Furthermore, sufficient beds must be provided for

the care of the sick during the winter and spring seasons of the year, when there is always an excessive number of such cases.

Scattered throughout the large camps or stations there will be dispensary buildings and dental clinics for the infirm care and dental treatment of the personnel. In addition, in each large camp there will be a medical headquarters, with properly qualified scientists for the general supervision of the medical activities, including the protection of the health of the troops, the careful inspection of food products and the general supervision of the nutrition of the men.

The Medical Department will be charged with the training of the medical detachments and the medical department units of the Regular Army and the National Guard, and with the instruction of the service personnel in hospitals and other installations. It is also responsible for the preparation of the trainees in enlisted replacement centers, in hospitals and in service schools, who will receive there the individual Medical Department instruction which will permit their incorporation in organizations for further unit training.

REQUIREMENT OF PHYSICIANS

The initial requirement will be approximately 6.5 doctors for each thousand men in the military service. Rapid calculation will show that the total number for an army of 1,400,000 men will be 9,100 doctors. Additional ones may be required, but in the interest of economy the initial procurement will be limited to the number stated. The 1,200 physicians in the Regular Army and the 1,100 in the National Guard are included in the total, leaving approximately 6,800 physicians to be supplied by the Reserve Corps. There are now in active service or under orders approximately 1,500 Reserve physicians, leaving 5,300 to be procured during the next few months.

STATUS OF THE RESERVE CORPS

Under the recent joint resolution passed by the Seventy-Sixth Congress, the President is authorized to order into the active military service of the United States for a period of twelve consecutive months each any or all members of any Reserve component of the Army of the United States, with or without their consent, to such extent and in such manner as he may deem necessary for the strengthening of the national defense. If a sufficient number of officers do not indicate their availability for this service, Reserve officers must necessarily be ordered to duty without their consent. Additional appointments among physicians of draft age will increase the strength of the Medical Corps Reserve. However, it is apparent that a large percentage of these officers must participate actively in the present program for preparing a portion of the country's man power for national defense.

In establishing rosters from which officers will be ordered to duty, corps area commanders and chiefs of

branches have been instructed to circularize all Reserve officers under their assignment jurisdiction to permit them to state the amount of deferment desired and the cogent, pertinent reasons for such deferment in the event that they are not immediately available for military service. This action has been taken in view of the fact that a national emergency has not been declared by the Congress, nor has mobilization been ordered. The medical service of a training program, although essential to national preparedness, possesses none of the glamour of the same service during actual military operations; it is, however, equally important. Indeed, military training may, through the thoroughness of its preparation for war, materially assist in preventing the necessity of participation in military operations. It is realized, of course, that all officers would express their immediate availability in the event of war; many, however, feel that their services are not of national importance at the present time.

Both the economic and the rational utilization of medical officers is essential. It is planned that as far as possible qualified officers will be selected for assignment to duty with units and at installations according to their previous training and experience. Accordingly, selection must be qualitative as well as quantitative in order that the specific requirements of a modern medical service may be properly met. Officers selected for duty will be given the maximum possible advance notice of such action.

INFORMATION FOR MEDICAL RESERVE OFFICERS ORDERED TO DUTY

In this connection the Surgeon General has suggested that the following points be brought to the attention of all Reserve medical officers:

1. When notified that you have been selected for active duty, submit at once the required report of physical examination. The disclosure of disqualifying

Pay and Allowances of Medical Reserve Officers

Grade	Annual Base Pay	Allowances			
		Rental Allowance		Subsistence Allow- ance (30 Days)	
		With Depen- dents	Without Depen- dents	With Depen- dents	Without Depen- dents
Colonel.....	\$4,000	\$120	\$80	\$36	\$18
Lieutenant Colonel..	3,500	120	80	54	18
Major.....	3,000	100	60	54	18
Captain.....	2,400	80	60	36	18
First Lieutenant.....	2,000	60	40	36	18

defects prior to the issuance of orders may prevent a disruption of your practice or civil employment.

2. Orders issued will place you on active duty at your home or, if a temporary change of address has been submitted, at that location, and will direct you to report to a specific post, camp or station for duty.

3. Travel to your station may be accomplished by automobile, but no delay will be granted for that purpose above the customary time for travel by rail.

4. You will be reimbursed for travel at the rate of 8 cents a mile, based on the shortest usual railway route to your station.

5. Transportation for dependents to your first station will not be furnished by the government. It is perhaps advisable that your family not accompany you, since the housing problem at or within the vicinity of Army stations is frequently acute.

6. If you have no uniform and military equipment, these may be purchased at your first station.

7. Pay and allowances are as shown in the accompanying table.

The annual base pay is increased at the rate of 5 per cent thereof for each three years of service up to thirty years. Full time will be computed for all periods during which men have held commissions as officers in the Army, Navy, Marine Corps, Coast Guard, Coast and Geodetic Survey and Public Health Service, or in the National Guard or Naval Militia, the National Naval Volunteers or the Naval Reserve Force or Marine Corps Reserve, when confirmed in grade and qualified for all general service, and with full time for all periods during which they have performed active duty under Reserve commissions, and with one-half time for all other periods during which they have held Reserve commissions.

PHYSICIANS UNDER SELECTIVE SERVICE

Physicians as a group will not be exempt from conscription for military training and service. Their deferment because of importance to civil communities is a function of the local draft boards. Accordingly, it is difficult to approximate the number which will be inducted into the Army. Obviously, the training received by such draftees will be more appropriate and the services rendered the Army of greater value if the physicians who are eligible and qualified for appointment in the Medical Corps Reserve be commissioned in the Officers Reserve Corps for duty as medical officers, rather than continue their training as enlisted men.

Physically qualified graduates of approved schools of medicine who desire appointment in the Medical Corps Reserve for immediate active duty should make application to the commanding general of the corps area in which they reside. Such applications may be submitted either before or after selection for military training and service or after induction into the Army of the United States. No change in the classification of such applicants will, however, be made by local selective service boards until the actual letter of appointment has been received.

APPOINTMENTS IN THE MEDICAL CORPS

Appointments in the Medical Corps of the Regular Army will, in all probability, continue as at present through competitive examinations of Reserve officers who have not passed the age of 32 years at the time of appointment.

WORK OF THE AMERICAN MEDICAL ASSOCIATION

The Surgeon General of the Army, through Lieut. Col. George C. Dunham, the representative of the Medical Department in the House of Delegates, submitted a request to that body at its last meeting in New York, in June 1940, requesting the assistance of the American Medical Association in the classification and procurement of physicians for the Army. It was hoped in this way to procure the physicians required without disturbing too seriously the civilian medical service and at the same time to place the physicians enrolled in positions for which their previous training qualified them. The House of Delegates approved the request of General Magee and appointed a Medical Preparedness Committee. The U. S. Navy and the U. S. Public Health Service made similar requests.

Reference has been made to the action of the House of Delegates and to the working of the Preparedness Committee in previous issues of THE JOURNAL. The Preparedness Committee, the executive officers of the American Medical Association and the chairman and

members of the various state and local committees have all given generously of their time and funds in this work. They have been of material assistance to the Surgeon General and corps area surgeons in the classification and procurement of Reserve Corps medical officers. They generously have offered their assistance in similarly classifying and procuring such physicians as may be required in addition to those in the Reserve Corps. Although the majority of appointments of additional Reserve officers for active duty at this time will be 35 years of age or under, a limited number of properly qualified physicians above this age will be required as chiefs of services of the many large hospitals to be established.

COOPERATION OF MEDICAL PROFESSION

The history of our country has repeatedly shown that there is no more patriotic group than the American physicians. They have always responded generously to

their country's call for assistance. At this time, although this country is not engaged in war, the national preparedness program requires an adequate medical service. Without it, the program will be hampered materially. In addition to the adequate care of the sick and protection of the health of our young men in the camps, the Medical Department must be able to train its personnel to act in conjunction with the troops of the other arms and services so that in time of battle, if unfortunately that time should come, it may be able to collect efficiently and evacuate promptly casualties that occur on the battlefield so that each one may receive as promptly as possible efficient medical care. Let us repeat: The success of the national preparedness program depends to a large extent on adequate medical service. American medicine appreciates its obligations and will furnish a sufficient number of properly qualified physicians.

CONFERENCE ON MEDICAL PREPAREDNESS HELD AT AMERICAN MEDICAL ASSOCIATION HEADQUARTERS, SATURDAY, NOV. 23, 1940

The following were in attendance:

Dr. Irvin Abell, chairman, presiding.	Brig. Gen. A. G. Love.
Dr. James A. Crabtree.	Dr. John H. O'Shea.
Dr. Charles A. Dukes.	Dr. Stanley H. Osborn.
Lieut. Col. George C. Dunham.	Dr. James E. Paullin.
Dr. Morris Fishbein.	Dr. Walter G. Phippen.
Dr. Roy W. Fouts.	Lieut. Col. C. B. Spruit.
Lieut. Col. C. G. Hutter.	Dr. Harvey B. Stone.
Dr. R. G. Leland.	Dr. Nathan B. Van Etten.
	Dr. Olin West.

FORENOON SESSION

Communications were read from Dr. Frederick Rankin of Kentucky and Dr. Samuel E. Thompson of Texas, who were unable to be present.

Remarks on Progress by Corps Area Representatives

Dr. Paullin said that the problem at present in the Fourth Corps Area concerned the distribution of physicians in counties where there were few doctors. They are preparing in those counties for medical care. Problems have arisen in North Carolina, South Carolina and Georgia concerning medical reserve corps officers who have been called into service with the possibility that their communities will lack sufficient medical service. An attempt has been made to settle the problem in each state and Dr. Paullin stated that Georgia has settled it. The second problem in the Fourth Corps Area is that of residents in teaching hospitals where some have been ordered to active duty; the suggestion has been made that they can operate as well with a slightly diminished personnel if those who remain will do a little more work. Through the state and local chairman, all members of the profession are being listed as to whether they can be spared from their communities and the lists are to be given to the corps area surgeons. The medical preparedness organizations have not as yet been functioning well in North Carolina and South Carolina.

Dr. Osborn and Dr. Phippen said that in the First Corps Area they have given the selective service and the local recruiting office all the assistance they have asked for in the way of induction and draft board physicians. A problem that confronts them in Massachusetts in completing the survey questionnaire is that of 2,400 nonmembers of the Massachusetts Medical

Society, including a lot of men from nonaccredited medical schools. Dr. Abell asked whether these men from nonaccredited schools would be eligible for commissions, and Brig. Gen. Love stated that they are not eligible now.

Dr. Dukes said that in the Ninth Corps Area questionnaires have been slow coming in because of the great distances involved; also some of the younger men hesitate to sign, fearing it will put them under obligations that they do not want to assume at present. The distances involved have made a difficult problem of supplying physicians for the boards also, although the necessary number has been provided. This difficulty does not affect California as much because of the larger number of physicians available. Dr. O'Shea said that members of the Washington State Medical Society had answered the questionnaire 100 per cent and that the entire state had returned now, 93 per cent. The problem of induction boards in the northern part of the Ninth Corps Area has been difficult. The board at Missoula, Mont., had to be drawn from the breadth of the entire state. The same situation existed at Boise, Ida., where there were not sufficient specialists for the induction board. At Vancouver it was necessary to get some specialists from Portland, Aberdeen and Noquiam.

Dr. Stone reported that the induction boards had been completed in the whole Third Corps Area. With regard to the survey questionnaire, there has been much difficulty in this area in physicians not receiving the questionnaire. Great interest has been shown by hospitals and medical schools about possible disruption of their staffs by the drafting of house men. Assurance has been given that the draft officers will use discrimination so that no institution will be badly disorganized by inductions from its staff. The availability of some physicians in some communities in the Third Corps Area, as well as some health officers, came up. Dr. Osborn pointed out that the state health officers in conference with the three surgeon generals agreed that the state health officers would forward to the U. S. Public Health Service, which would forward to the surgeon generals of the army and navy, a list of health officers who it was felt were indispensable to maintain civilian health. Each state health officer has

already sent a list of indispensable employees to the U. S. Public Health Service. These lists were sent to the surgeon general of the army, who has sent copies of them to the corps area surgeons. General Love said that some of these lists apparently had been turned over to subordinates, who included in the list not only the key man but all of the men, even nurses and technicians.

Dr. Fouts of the Fourth Corps Area reported that 83.8 per cent of the survey questionnaires had been returned. Nebraska had returned 97 per cent. He supplied a list of men for the draft boards to the Adjutant General of the National Guard, Nebraska, which was submitted to the governor. Thus far he has made no recommendations for appointments on the medical advisory boards in Nebraska. He has furnished the corps area surgeon with adequate lists of specialists for service on the induction boards and at the next call in January each board will make its own arrangements with men on this list who have agreed to the call, understanding that they would not serve several days in succession but a day at a time, if possible. Dr. Fouts said that he could not provide four neuropsychiatrists for the induction boards if it requires a week or ten days of their time to go great distances away from home. There are not four neuropsychiatrists, he said, in the state of North Dakota, and how he is to get four for the board at Fort Crook is a question. An adequate panel has been turned over to the corps area surgeon for the induction boards on whom his induction board administration can call.

Colonel Spruit pointed out that it does not require four men for a board but one psychiatrist at the rate of every fifty inductants examined.

Dr. Fishbein said that in the sparsely settled states one psychiatrist would be able to give the psychiatric examinations. Circular No. 1 defined the examination simply as sufficient to rule out insanity but not the kind of examination that the average psychiatrist thinks of making when he makes an examination for legal purposes.

Dr. West said that apparently this problem in New York had been well attended to and the demands of the corps area satisfied. In New Jersey the committee has been active, but they have had some difficulties having to do with the selection of examiners for local draft boards and for advisory boards. Some governors of states have called on state committees for a list of names for consideration for appointment as medical examiners and then have paid no attention to the recommendations submitted to them but in one or two instances have put on osteopaths. Dr. Fouts said it was true in Nebraska, where they had to work over the list the third time. Colonel Spruit asked to be informed concerning unqualified men who might be appointed as examiners. Dr. West said that the request was transmitted to every state chairman and members of the Committee on Medical Preparedness. Colonel Spruit should receive all the information available about unqualified men that have been nominated to serve in these capacities by governors of states, as he is anxious to keep such men off the boards as far as it is possible to do so.

Colonel Spruit said that incompetent physicians will show up in the results of their physical examinations, as he has had occasion to observe in the first reports of examinations from some states. One man was passed who was 6 feet tall and weighed 138 pounds, and

another accepted for the draft had a perforated ear drum, both causes of rejection. Incompetent physicians on these boards can be removed if the traveling inspectors believe they are not doing a good job. The examining physicians and appeal boards are under national control, and it may be that the medical advisory boards will be placed under national control.

Dr. West said that a few men had already been commissioned in the reserves and assigned to active duty for whom the A. M. A. headquarters had no record whatever. The War Department had not asked these headquarters to check over the lists before these men had been commissioned or assigned to duty. General Love stated that they would be very glad to have a list of these names and to investigate them.

The committee asked that official lists of all physicians in selective service, and on local examining boards and medical advisory boards, and the legal member on the appeal boards be sent to the American Medical Association headquarters for checking by the Bureau of Investigation.

AFTERNOON SESSION

Report on Survey of Committee on Medical Preparedness

Dr. Leland reported on the survey being conducted by the Committee on Medical Preparedness. Since July 5, 126,489 schedules have been received. Of that number 81,853 have had the information transferred to punch cards. Of those 50,000 have been sorted in various ways for the listing of specialists, of general practitioners and of physicians in special classifications. The specialists have been listed by states for about 50,000 punch cards. Eighteen thousand general practitioners are now being listed on a specially devised form. The specialty lists are being sent to special committees that will provide the Committee on Medical Preparedness with additional information concerning residencies completed, recognized postgraduate work that the specialist has taken, and the qualifications of specialists as administrators and as teachers and research workers. Shortly, many more of these cards will be run and more names compiled on these listing sheets, giving information on additional numbers of physicians. Lists were received from some state chairmen of physicians for the Induction Boards in their areas and these were accepted at face value. Faculties of medical schools have provided the Committee with lists of teachers considered essential to the operation of the school. Many state chairmen have given much time to stimulating physicians to return their schedules. Some states have reached almost 100 per cent and others are still working diligently. Later, if a schedule from a physician over 70 years of age is not received, one will be filled out in the headquarters with the information contained in the American Medical Directory and placed in the files. Some of these men would be suitable for civilian medical care. Generally, the work in connection with the census is proceeding satisfactorily.

Questionnaires on Industrial Medicine

A special questionnaire was sent to all physicians who indicated that they were interested in devoting themselves to industrial practice. Dr. Leland thought that, when this particular survey is completed, about 6,000 industrial practicing physicians will be found.

This census will ultimately provide vast amounts of accurate and complete information which ought to be

put to some use. These headquarters are ready at all times to make the information available to those who need it.

Dr. Abell asked how many of the 126,000 replies received are from men within the active age limit. That information has not been attained yet. Dr. Fishbein, however, stated that he had figured this out for another purpose and found that there were approximately 14,000 physicians in the United States over 60 years of age. Dr. Leland stated that few of the older men refused to volunteer but that a large number of younger men will not or are undecided unless it comes to a matter of immediate war, when they would volunteer at once.

General Love stated that the work done by the various committee men will be a great help to solve the problem of supplying physicians. The idea is for them to have a year of service and then go back and have some one else take their place, unless we get into actual war and unless the physician requests an extension of service.

Dr. Crabtree said that the U. S. Public Health Service would like to have access to these data in case it needs to increase its personnel, as there may be occasion to employ other types of specialists, particularly in tuberculosis and venereal disease and possibly industrial medicine. As yet, Dr. Leland stated, lists on public health specialists or tuberculosis have not been drawn.

The committee voted to accept Dr. Leland's report and adopt it as the official record of the Committee on Medical Preparedness so far in this work.

Fee Schedule for Laboratory and Roentgen Examinations

A subcommittee of the Committee on Medical Preparedness composed of Dr. West, Dr. Fishbein and Dr. Leland previously was appointed to prepare a fee schedule for laboratory and roentgen examinations. The subcommittee obtained a schedule that had been prepared for the state of New York and sent copies to each member of the Committee on Medical Preparedness, each state chairman and the secretary of each state medical association. The committee did not approve this schedule unanimously by mail vote. The selective service system decided that it might be better to have a fee schedule for each state and instructed the state headquarters of the selective service system to confer with the medical societies about formulating schedules and that action relieved the subcommittee of the Committee on Medical Preparedness of responsibility of preparing a fee schedule to be applicable throughout the country.

Dr. West said that those schedules have been returned to him by individual men in various states with notations that some fees on the New York schedule are too high. Dr. Van Etten said that they are a little less than half of the fees provided in the workmen's compensation law in New York and that the laboratory men there were willing to make this concession as a patriotic contribution.

It was moved and voted that the schedules for laboratory and examination fees be left to the individual states and that the subcommittee of the Committee on Medical Preparedness appointed to prepare a fee schedule be discharged.

Corps Area Surgeons to Confer with Members of Committee or with State Chairman

After a discussion by various members present, it was voted that each state committeeman be responsible more or less for the affairs of his state committee through the corps area chairman of the Medical Pre-

paredness Committee and that both of them in cooperation work with the corps area surgeon to accomplish the desired ends or purposes of this committee and that all such information be communicated from one to the other.

Rejection of Registrants with Venereal Disease

General Love said that when the Committee on Medical Preparedness met, September 20, the arrangement at that time was for Wassermann tests to be taken of the registrants at the time of the induction and that all registrants with evidence of venereal lesions would be placed in a limited service class. The Surgeon General's Office considered this matter and decided that it would be better to have the blood specimens taken by the local draft boards, and since this is primarily a military training project, the army would not be warranted in taking in positive cases; that is the explanation of the reversal of policy in this matter as far as the War Department is concerned.

Colonel Spruit pointed out the advantages of having the blood specimens taken by the local boards rather than at the induction centers. Dr. Crabtree said that this procedure will provide a Wassermann dragnet that will find a great amount of syphilis and, if we take advantage of it by placing the positive cases under treatment, will advance syphilis control many years.

Dr. Fishbein said that if we could get, say by January, some statistics on the number of positive Wassermann tests in the first group and on the difficulties involved in applying serologic tests to the first group examined, it would indicate how to do it better when the large group comes along later. It may be necessary to modify some of the procedures fairly soon, and the sooner we learn what is to make these modifications necessary, the quicker the machinery can be set in motion to make the modifications. It is conceivable that by some other sudden order the whole venereal disease situation might be changed again.

It was voted that the remarks of General Love and Colonel Spruit covering this subject be made a part of the record of the Committee on Medical Preparedness.

Communities Deprived of Medical Service

Dr. Abell said that in a few locations in Kentucky and Tennessee some of the younger physicians in the Medical Reserve Corps have been ordered to active duty, leaving certain communities and hospitals deprived of men essential to carry on adequate medical service. The question of selecting men to be ordered to active duty without depriving communities of essential men was fully discussed. It was found that, as General Love stated, there had been a misunderstanding. Dr. West and Dr. Paullin pointed out that the purpose of the Committee on Medical Preparedness was to render definite help to the War Department in the selection of officers and to see that the civil communities were left with sufficient physicians to provide them with medical care. General Love stated that the corps area commanders had been directed to make a survey of reserve officers to determine those who volunteered for active service and those who could be spared from their communities, but that it was difficult for a corps area surgeon to know the requirements of the various communities in his area and to determine what men should be ordered to duty, especially if they volunteer. General Love said that we are trying to get physicians without disturbing practice in the hospitals and schools but that we have to work fast, as within the next three months about 20,000 additional hospital beds will be

opened and physicians must be had to man these military hospitals. We shall need then about 6,000 or 7,000. Dr. Fishbein stated that, if we could go before the profession with definite information about the number needed and the kind of work they need, they will be commissioned first lieutenants and paid so much, and that if their assignment to a hospital will count toward certification for an examining board it would probably be less difficult to get 5,000 physicians to volunteer. [This material appears in the current issue of *THE JOURNAL*.]

Dr. O'Shea asked whether reserve officers can still resign and General Love said that any one below the grade of captain might resign.

The motion made by Dr. Paullin that the Committee on Medical Preparedness go on record as furnishing to the Surgeon Generals of the Army, Navy and the Public Health Service a statement that the committee is willing to cooperate with them fully whether for preparedness or for war, after full discussion, was adopted.

Dr. Paullin also moved that each state committee chairman in consultation with the corps area surgeon study the members of the medical reserve corps in the various areas and, in cooperation with local or district committees, determine whether or not their services are indispensable for the community. This was discussed and adopted by the committee.

Graduates of Unapproved and Foreign Schools

Dr. Van Etten read a resolution from Kings County Medical Society, Brooklyn, which brought forth a discussion of whether men from foreign medical schools and from unapproved schools in this country should be commissioned. After discussion by various members, Dr. Fishbein pointed out that the Association, to be consistent, must support the standards of the Council on Medical Education and Hospitals, and that the Committee on Medical Preparedness could therefore only recommend that physicians who are graduates of acceptable American and Canadian schools be considered in selection for commissions. The motion was seconded and carried.

The National Youth Administration

Dr. Crabtree said that the Public Health Service had assigned to each corps area a liaison commissioned officer to expedite relations between the War Department and the public health interest of the communities; they will report for duty December 1 and in any way in which they can be of service to the Committee on Medical Preparedness or the state or local communities, they are available. The Public Health Service is already meeting the usual problems of prostitution, general health and sanitation services, medical service and hospital service in communities adjacent to army camps and industrial developments. These problems have stepped up tremendously in some of these areas, and the Public Health Service needs help.

Dr. Crabtree said that the National Youth Administration has changed its program and now is emphasizing training youth in vocations in essential defense industries. The National Youth Administration asked the Public Health Service to develop a health program for these boys under training, and a medical officer was assigned to see what could be done. In the next year it is estimated that 500,000 youths between 18 and 25 will pass under this supervision and that 60 per cent of them are indigent. This program falls into two

categories: (1) a resident project, (2) a nonresident project. In the former the youth is taken from home to some center and put in a dormitory and given vocational training and from \$6 to \$8 a month. Of these there will be some 100,000. The other 400,000 will live at home but work or go to school locally. The health program as proposed includes a physical examination and an attempt to rehabilitate the boy as far as practicable. In the resident centers they propose to employ a nurse and local physicians.

Dr. Fishbein said that the National Youth Administration is apparently attempting to carry out a medical program without telling the medical profession what it is doing. It should draw up a statement of what it is attempting. He did not think the medical profession objected to helping to take care of these boys. If the National Youth Administration would get to the profession word of what is needed, it will probably get all the cooperation it desires.

Protection of Interests of Physicians Called Into Service

Dr. West said that some communities are working on plans for looking after the interests of doctors called into active service. Dr. Dukes moved that the Committee on Medical Preparedness approve of the activities in certain states with regard to the protection of men who go to service and to approve also of what has been done to protect them legally and that the committee further study this problem and give all assistance possible to men called into service. The motion was seconded and approved.

Status of Interns and Medical Students

Dr. Abell read a letter from the Greater New York Hospital Association addressed to Col. Arthur McDermott, indicating that they had already agreed that the interns and residents in New York hospitals will, under his control, be deferred; that, he said, is what can be done in each state if one wants to by taking it up with the Selective Service headquarters in the state. Dr. Phippen said that this procedure was considered in Massachusetts, where they decided that it would be better to take each individual intern as he came up before his draft board. The Massachusetts Medical Society and the Massachusetts Hospital Association appointed a joint committee to consider such matters. Dr. West brought out that the Surgeon General had said that interns who wish to apply for commissions in the Medical Reserve Corps will be accepted if they can qualify but that they will not be assigned to active duty until they have completed their one year of internship.

Dr. Fishbein moved that the Committee on Medical Preparedness urge on all interns and residents the desirability of a year of service and that a statement be requested from the Surgeon General outlining the circumstances under which interns will be granted reserve commissions. General Love replied that such a recommendation has already been approved in the Surgeon General's Office and is now on the desk of the Chief of Staff of the Army. Furthermore, if an intern is drafted he is still eligible for a commission in the Army, but the Army ordinarily would not call him out until after he had completed his one year's internship. However, that regulation can be changed at any time. Further discussion brought out that the Navy will commission a doctor the day after graduation and give him an internship in a navy hospital. Dr. Abell said

that a number of the specialty boards appear favorable, although no definite action has been taken, to granting recognition for the year spent in that service as applied to their training. Dr. Stone said that the American Board of Surgery had agreed to that in principle with the reservation that if a man desires his service in the Army to apply to certification it would have to be of a surgical nature and not a year of general service in the Army.

Collection of Blood For Transfusion Purposes

After discussion it was moved and voted that the collection of blood for transfusion purposes be referred to a committee of the National Research Council.

Staff Personnel for New Army Hospitals

General Love said that there are to be about 70,000 hospital beds, including those now in use, and one fifth of these will be in general hospitals and the other four fifths in camp hospitals on a 4 per cent basis in each camp and varying in size from 500 beds to 2,000 beds. Between fifty and sixty doctors per thousand beds will be required. With the 20,000 beds already available in army hospitals, about 50,000 additional beds will be

provided for. The present age limit for physicians to man these army hospitals is 55 years; there is a possibility that this service may not be limited to one year but may extend to several years.

Dr. Dukes moved that the Committee on Medical Preparedness study this problem and be prepared to nominate from the various districts such men as might be required beyond draft age for the specialty groups that may be called on for the government. The motion was put to a vote and carried.

Letters

Letters were read to the committee from the Dental Preparedness Committee of the American Dental Association, from the National Medical Association and from the secretary of the New York State Medical Association, all of which were discussed. A letter was read also concerning roentgen examination of the chest of drafted men and a badge for physicians serving as examiners but not holding commissions. Dr. O'Shea moved that the subject of the badge be referred to the Executive Committee of the Committee on Medical Preparedness to report back at the next meeting. The motion was carried.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

WAR DEPARTMENT

Following is a list of additional medical reserve corps officers who up to November 25 had been ordered to extended active duty with the regular army by direction of the War Department, Washington, D. C.:

APPLEBAUM, Henry, 1st Lieut., New York.
ARMSTRONG, James Harris, 1st Lieut., Oxford, Miss.
BAGNALL, William Stanley, 1st Lieut., San Francisco.
BLOOM, Rudolph, Colonel, Philadelphia.
BOOTH, Edgar Waldo, 1st Lieut., Shreveport, La.
BROWN, Thomas Paul, 1st Lieut., Drexel Hill, Pa.
BURNSTINE, Marcus David, 1st Lieut., Columbus, Ohio.
CASEY, David Timothy, 1st Lieut., Cambridge, Mass.
CHAIN, William Thomas, 1st Lieut., Narberth, Pa.
DENHAM, Robert Hilliard, Jr., 1st Lieut., Grand Rapids, Mich.
ENGELHARDT, David Meyer, 1st Lieut., Warren, Wyo.
FANTUS, Robert Alan, 1st Lieut., Chicago.
FEIMAN, Lawrence Holt, 1st Lieut., Milwaukee.
GARDNER, Leon Philip, 1st Lieut., Aurora, Ill.
GOERINGER, Claire Ferdinand, 1st Lieut., Wilkes-Barre, Pa.
GOLD, Jacob Louis, Captain, New York.

GOLDSTEIN, Isadore Irwin, 1st Lieut., Chicago.
GRINDLAY, John Happer, 1st Lieut., Rochester, Minn.
HAINES, John Wister, 1st Lieut., Philadelphia.
HALL, Robert Milton, 1st Lieut., Denver.
JONES, Warren Candler, 1st Lieut., Sunflower, Miss.
KELLY, Delbert Cleo, 1st Lieut., Hazel Dell, Ill.
KETCHUM, Clarence Wood, 1st Lieut., Atlanta, Ga.
KOLCZUN, Michael Cornelius, 1st Lieut., New Orleans.
LARCHEZ, Albert Robert, 1st Lieut., Arlington, Mass.
LIPSON, Herbert Jacob, 1st Lieut., Grafton, N. D.
MARSHALL, James Moore, 1st Lieut., Conway, S. C.
MATHIS, Earl Nadeau, 1st Lieut., San Francisco.
McCARTHY, Alphonsus Melvin, Major, Electric Mills, Miss.
POWER, William Redmond, 1st Lieut., Merrick, L. I., N. Y.
PRIEST, Allan Eugene, 1st Lieut., Pullman, Wash.
REICHARD-ESTEVES, William, 1st Lieut., Des Moines, Iowa.
RIZZOLO, John, 1st Lieut., Newark, N. J.
SASEEN, Charles Allen, 1st Lieut., Atlantic City, N. J.
SCHOFIELD, John Thomas, Jr., 1st Lieut., Philadelphia.
SVETICH, Edward Michael, 1st Lieut., Joliet, Ill.
TALBOT, John Ralph, 1st Lieut., Marshfield, Wis.
VAN ARSDALL, Condit Brewer, Jr., 1st Lieut., Harrodsburg, Ky.

NINTH CORPS AREA

The following medical reserve officers were ordered to extended active duty by Ninth Corps Area Order for the week ended November 23. The Ninth Corps Area comprises the states of Washington, Montana, Wyoming, Oregon, Nevada, Utah, California and Idaho:

ALTOSE, Alexander R., 1st Lieut., Seattle, Fort Lewis, Wash.
BOLSTAD, Donald S., 1st Lieut., The Dalles, Ore., Fort Lewis, Wash.
COGGIN, Charles B., Captain, Los Angeles, Presidio of Monterey, Calif.
CUSTER, Clarence P., Captain, Patterson, Calif., Presidio of Monterey, Calif.

DARRAH, John R., Captain, Cody, Wyo., Fort Lewis, Wash.
GARDENIER, William H., 1st Lieut., Los Angeles, Presidio of Monterey, Calif.
HARRISON, Alexander V., 1st Lieut., Los Angeles, Fort Lewis, Wash.
KESSLER, Raymond L., Captain, Pendleton, Ore., Fort Lewis, Wash.
MINNA, John B., Major, San Diego, Calif., Presidio of Monterey, Calif.
PRESENT, Arthur J., 1st Lieut., La Jolla, Calif., Presidio of Monterey, Calif.
SCHWARTZ, Irving, Jr., Captain, San Francisco, Presidio of Monterey, Calif.
SHORT, Faulkner A., 1st Lieut., Portland, Ore., Fort Worden, Wash.
WILEY, James W., 1st Lieut., Portland, Ore., Fort Worden, Wash.

NAVAL RESERVE OFFICERS ORDERED TO ACTIVE DUTY

The following medical officers of the U. S. Naval Reserve are under orders for active duty, in addition to the names of those published in THE JOURNAL, November 16. Their rank, home address and station are indicated:

CASON, William M., Lieut. Comdr., Sandersville, Ga., Naval Air Station, Jacksonville, Fla.
CONSTANS, George M., Lieut. Comdr., Bismarck, N. D., State Director of Selective Service, North Dakota.
CRISPELL, Raymond S., Lieut. Comdr., Durham, N. C., Norfolk Naval Hospital, Portsmouth, Va.
DEYTON, John W., Lieut., Asheville, N. C., Naval Air Station, Pensacola, Fla.
GILLEN, James H., Jr., Lieut., Arlington, Va., Nav. Med. Sch., Nav. Med. Center, Washington, D. C., for instruction.

JAMESON, Edwin M., Lieut. Comdr., Saranac Lake, N. Y., Nav. Med. Sch., Nav. Med. Center, Washington, D. C., for instruction.
KENNEDY, Thomas J., Lieut. Comdr., Washington, D. C., Naval Reserve Aviation Base, Anacostia, D. C.
McCARTHY, Lawrence J., Lieut. Comdr., Boston, Naval Hospital, Chelsea, Mass.; continue duty.
RICCIARDI, Ignatius J., Lieut. (j. g.), Milwaukee, Wisconsin and Upper Peninsula of Michigan, less the Superior area.
WIESINGER, Warren E., Lieut. (j. g.), Oakland, Calif., Receiving Ship, San Francisco.
WILSON, Merton Clarke, Lieut. Comdr., Detroit, Lower Peninsula of Michigan, plus Toledo area.
WIPPERMAN, Frederic F., Lieut. (j. g.), Minneapolis, Naval Reserve Air Base, Minneapolis.
WITWER, Russell G., Lieut. (j. g.), Cleveland Heights, Ohio, Northern part of Ohio, less Toledo area.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The thirty-seventh Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, Feb. 17 and 18, 1941. Topics to be discussed include the place of the medical profession in the program of national defense, adjustment of medical education to social demand, coordination of professional education in medicine and allied fields, the teaching of public health and of surgery, education of Negroes, nomenclature, function of the museum in the medical school, a naturopathic subterfuge, and developments in the field of dental education. A tentative list of speakers follows:

Raymond Allen, M.D., Executive Dean, Professional Schools, University of Illinois, Chicago.

William Boyd, M.D., Professor of Pathology and Bacteriology, University of Toronto, Ontario.

C. Sidney Burwell, M.D., Dean, Harvard Medical School, Boston.

Oliver C. Carmichael, LL.D., Chancellor, Vanderbilt University, Nashville, Tenn.

Haven Emerson, M.D., formerly executive officer of the Delamar Institute of Public Health, Columbia University.

Rt. Rev. Maurice F. Griffin, LL.D., Trustee, American Hospital Association, Cleveland.

Samuel C. Harvey, M.D., Professor of Surgery, Yale University School of Medicine, New Haven.

Mr. J. W. Holloway Jr., LL.B., Acting Director, Bureau of Legal Medicine and Legislation, American Medical Association, Chicago.

Edwin P. Jordan, M.D., Assistant Editor, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago.

Chauncey Leake, Ph.D., Professor of Pharmacology, University of California Medical School, San Francisco.

Edward L. Turner, M.D., President, Meharry Medical College, Nashville, Tenn.

Lewis H. Weed, M.D., Chairman, Division of Medical Sciences, National Research Council, Baltimore.

Ray Lyman Wilbur, M.D., Chairman, Council on Medical Education and Hospitals, American Medical Association, Stanford University, Calif.

The Federation of State Medical Boards of the United States will participate in the congress, covering such subjects as basic science laws, the National Board of Medical Examiners as related to medical licensure, the status of the internship, the legal status of the physician and practice violators. Among the speakers will be:

Charles Carter, Ph.D., Chairman, Iowa Board of Examiners in the Basic Sciences, Fairfield.

Mr. E. S. Elwood, Executive Secretary, National Board of Medical Examiners, Philadelphia.

Reginald Fitz, M.D., Assistant to the Dean, Harvard Medical School, Boston.

I. D. Metzger, M.D., Chairman, Pennsylvania Board of Medical Education and Licensure, Pittsburgh.

Julian F. Du Bois, M.D., Secretary and F. Manley Brist, LL.B., Attorney, Minnesota Board of Medical Examiners, St. Paul.

Dr. Ray Lyman Wilbur, President of Stanford University, will be the guest speaker at the Annual Dinner of the Federation.

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the A. M. A. meeting at Cleveland on June 3, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take

the programs at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and broadcast it at another hour or even on another day. It is advisable therefore to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme, the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in THE JOURNAL and monthly in Hygieia, the Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

December 11. The Family's First Friend.

December 18. A Stitch in Time.

December 25. The Country Doctor.

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

Dec. 10—University of Michigan Public Health Assembly, Ann Arbor.

Dec. 13—Will-Grundy County Medical Society, Joliet, Ill.

Dec. 16—Wells High School, Chicago.

DR. MORRIS FISHBEIN:

Dec. 12—Allegany-Garrett County Medical Society, Cumberland, Md.

Dec. 12—Cumberland Forum, Cumberland, Md.

Dec. 15—Newton Community Forum, Newtonville, Mass.

Dec. 16—Merrill Institute and Free Lecture Association, Exeter, N. H.

Dec. 17—Pharmaceutical Advertising Directors Club, New York.

Jan. 3—Academy of Medicine of Toledo and Lucas County, Toledo, Ohio.

DR. FRANK H. LAHEY:

Dec. 10-12—Southern Surgical Society, Hot Springs, Va.

Dec. 16—Fulton County Medical Society, Atlanta, Ga.

Dec. 19—Gloucester County Medical Society, Woodbury, N. J.

DR. CARL M. PETERSON:

Dec. 19—Section on Industrial Health of the Philadelphia County (Pa.) Medical Society.

DR. PAUL A. TESCHNER:

Dec. 9—Y. M. C. A., Central Branch, Chicago.

Dec. 18—Lincoln Park Kiwanis Club, Chicago.

DR. NATHAN B. VAN ETEN:

Dec. 7—Bronx Medical Association, New York.

Dec. 12—Linn County Medical Society, Cedar Rapids, Iowa.

Dec. 17—Monroe County Medical Society, Rochester, N. Y.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Nicholas H. Dejanney, Detroit, has been appointed a member of the tuberculosis staff of the state department of health of Alabama.

Regional Meeting.—The Northwestern Division of the Medical Association of the State of Alabama met in Reform, October 10, with the following speakers: Drs. Frederick W. Wilkerson, Montgomery, "Cardiac Neuroses"; James S. Snow, Birmingham, "Drug Eruptions"; Joseph Alston Maxwell, Tuscaloosa (subject not announced); John W. Simpson, Birmingham, "The Child's Little Stomach," and David H. Wright, Berry, "Coronary Thrombosis."

CALIFORNIA

Symposium on Military Preparedness.—A symposium on military preparedness constituted the program of the Los Angeles County Medical Association at its meeting, November 7; the speakers were Judge Peirson M. Hall, selective service board; Rear Admiral David C. Cather, the navy, and Major John F. Bohlender, the army.

The Physician and the Military Emergency.—The San Francisco County Medical Society, San Francisco, devoted its meeting, November 12, to a symposium on "The Physician in Our Present Military Emergency." Dr. Philip K. Gilman, chairman of the state committee on medical preparedness, opened the meeting. Other speakers were Dr. Charles A. Dukes, Oakland, representing the selective service board; Dr. Herbert D. Crall, the army; Capt. Edward U. Reed, the navy, and Comdr. Clinton C. Defoney, the air corps.

FLORIDA

In Memory of Dr. Joseph Porter.—A housing project consisting of 136 family units will be called the Joseph Y. Porter Place to honor a physician who for many years before his death was state health officer. The project, named by the Key West Housing Authority, will be situated on recently purchased property on Trumbo Island, according to the state medical journal. Dr. Joseph Yates Porter graduated at Jefferson Medical College of Philadelphia in 1870 and in the same year was appointed assistant surgeon in the army. He was in charge of government relief measures during the yellow fever epidemic in Jacksonville in 1888 and was one of the first to support the mosquito transmission theory of yellow fever. He was appointed deputy surgeon general with the rank of lieutenant colonel and in 1907 was retired by Act of Congress. Among other positions, Dr. Porter served as quarantine inspector for the U. S. Public Health Service; president of the Florida Medical Association; for some thirty years state health officer; president of the state and provincial boards of health, 1909-1910, and camp surgeon at Camp Joseph E. Johnston during the World War. He was 79 years of age when he died, March 16, 1927.

ILLINOIS

District Meeting.—The Sangamon County Medical Society held a joint meeting with the District Medical Society of Central Illinois at St. John's Hospital in Springfield, November 7. Participating in the program were:

- Dr. Sidney O. Levinson, Chicago, Serum Transfusions or Blood Transfusions?
- Dr. Frederick A. Jostes, St. Louis, Manipulative Treatment of Backache.
- Dr. Louis H. Jorstad, St. Louis, Surgery or Radiation in Cancer of Skin and Mouth.
- Dr. Ralph H. Major, Kansas City, Mo., Changing Picture of Therapy in Pneumonia.
- Dr. Thomas D. Masters, Springfield, Chronic Peripheral Artery Disease.
- Dr. Robert J. Patton, Springfield, Endometrioma of Sigmoid with Obstruction.
- Dr. Henry S. Dickerman Jr., Springfield, The Thyroid Heart.

Chicago

Gifts to Northwestern University.—Northwestern University has received \$635,000 from the estate of the late Dr. John S. Appleman, it is reported; \$135,000 is restricted to use of the medical school clinics. Announcement has also been

made of a gift of \$162,000 from the Clara A. Abbott trust for advancement of medical, chemical and surgical science. Mrs. Abbott, widow of Dr. Wallace C. Abbott, founder of the Abbott Laboratories in North Chicago, previously had given the university \$1,500,000 for similar purposes.—A gift of \$50,000 from Miss Edith L. Patterson, Sterling, Ill., as additional endowment for the Patterson cancer clinic at Passavant Hospital, Northwestern University, was recently announced.

Society News.—The Chicago Urological Society was addressed, November 28, by Drs. Joseph H. Kiefer on "Tumors of the Testicle: Hormone Determinations in Diagnosis and Management"; Gustav Kolischer, "The Irritable Bladder," and Fay H. Squire, "Deep Roentgen Therapy in Elusive Ulcer of the Bladder: An Analysis of Twenty-Five Treated Cases."—Dr. John Alexander, Ann Arbor, addressed a joint meeting of the Chicago Tuberculosis Society and the Illinois chapter of the American College of Chest Physicians, November 18, on "Management of Bronchiectasis."—The Chicago Laryngological and Otolological Society was addressed, December 2, by Drs. Elmer W. Hagens on "Otosclerosis in Identical Twins" (case report) and Stuart C. Cullen, Iowa City, "Anesthesia in Otolaryngology."

INDIANA

State Medical Election.—Dr. Maynard A. Austin, Anderson, was chosen president-elect of the Indiana State Medical Association at its recent annual meeting in French Lick. Dr. Albert M. Mitchell, Terre Haute, will take office as president January 1. Indianapolis was selected as the place for the 1941 annual session.

Society News.—Dr. Thurman B. Rice, Indianapolis, discussed poliomyelitis before the Huntington County Medical Society, Huntington, October 2.—The Fountain-Warren County Medical Society was addressed in Kramer, October 3, by Dr. Frank W. Cregor, Indianapolis, and Mr. Thomas A. Hendricks, Indianapolis, on "United Efforts of the Medical Profession."—Dr. Russell L. Haden, Cleveland, addressed the Tippecanoe County Medical Society in Lafayette, October 8, on "Pathologic Hemorrhage and Blood Dyscrasias."—Dr. William F. King, Indianapolis, presented "Clinical Pictures of Blood Dyscrasia" before the Hendricks County Medical Society in Danville, October 24.—Lieut.-Col. Robinson Hitchcock, on the staff of the adjutant general's office, state of Indiana, discussed "National Defense and the Indiana Selective Service Plan" before the Indianapolis Medical Society, November 12. Dr. Norman E. Freeman, Philadelphia, addressed the society, November 26, on "Peripheral Circulatory Failure: Its Prevention and Treatment."

MARYLAND

Joint Psychiatric Meeting.—The Maryland Psychiatric Society and the neuropsychiatric section of the Baltimore City Medical Society will hold a joint session at Towson, December 12. Dr. Max Levin, Baltimore, will speak on "Pathogenesis of Narcolepsy" and Dr. Lawrence F. Woolley, Towson, "Technic of Curare-Metrazol Therapy."

The De Lamar Lectures.—Johns Hopkins University School of Hygiene and Public Health announced the following program for the 1940-1941 series of De Lamar Lectures:

- Dr. Virgil P. W. Sydenstricker, Augusta, Ga., November 19, Dietary Problems of the Southern United States.
- Otto A. Bessey, Ph.D., Boston, November 26, Morphological Defects in Dietary Deficiency States.
- George R. Cowgill, Ph.D., New Haven, Conn., December 3, Nutritional Deficiencies in Tropical America.
- Dr. Edward H. Hatton, Chicago, February 18, Etiology of Dental Caries.
- Dr. Max Theiler, New York, March 4, Studies on Poliomyelitis.
- Dr. Charles N. Leach, Montgomery, Ala., March 18, Recent Studies on the Epidemiology of Rabies.

MASSACHUSETTS

New Health Commissioner of Boston.—Dr. George Lynde Gately, Boston, has been appointed health commissioner of the city of Boston. He succeeds Dr. Henry F. R. Watts, who has retired on a pension after having served the city thirty-one years in different capacities. Dr. Gately graduated at Tufts College Medical School, Boston, in 1918. He is 46 years of age.

Society News.—Dr. Donald Ewen Cameron, Albany, N. Y., addressed the New England Society of Psychiatry, November 13, in Northampton on "Influence of the Times on the Teaching of Psychiatry."—Dr. Morris J. Nicholson, Boston, will speak on "Fractional Spinal Anesthesia" before the New England Society of Anesthesiology in Boston, December 10.

Dr. Albert H. Miller, Providence, R. I., addressed the society, November 12, on "Mechanics of Gas Anesthesia."—Among others, Dr. Francis S. Cheever, Boston, discussed "Observations on the Brown-Pearce Carcinoma in Roller Tile Tissue Cultures" before the Boston Society of Biologists, November 20.

MICHIGAN

Outbreak of Smallpox.—Two cases of smallpox have been reported in Detroit and 5 in Highland Park, newspapers announced November 16. These cases, the first reported in Detroit in three years, prompted Henry F. Vaughan, Dr.P.H., health commissioner, to urge all persons who have not been successfully vaccinated for smallpox within the last five years to have it done at once, it was said. There were 371 cases in the state in 1939 and 25 cases during the first eight months of 1940.

The Dr. Max Ballin Memorial Lectures.—The first lecture in the annual series sponsored by the North End Clinic, Detroit, in memory of Dr. Max Ballin was delivered, November 27, by Dr. August A. Werner, assistant professor of internal medicine, St. Louis University School of Medicine. His subject was "Recent Advances in Endocrine Therapy." The second lecture was given, December 4, by Dr. Walter C. Alvarez, Rochester, Minn., on "Recent Advances in Treatment of Food Allergy," and the last, December 11, will be by Dr. Harold J. Jeghers, Boston, assistant professor of medicine, Boston University School of Medicine, "Recent Advances in Vitamin Therapy."

NEW JERSEY

Society News.—Dr. Charles W. Mayo, Rochester, Minn., addressed the Bergen County Medical Society, Englewood, November 12, on "Surgical Treatment of Malignancy of the Right Colon."—Dr. Edward A. Strecker, Philadelphia, addressed the Camden County Medical Society, Camden, November 5, on alcoholism.—Dr. Edward Weiss, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, November 8, on "Recent Advances in Hypertension and Kidney Disease."—Dr. Tracy J. Putnam, New York, was the speaker at a joint meeting of the Academy of Medicine of Northern New Jersey and the New Jersey Neuropsychiatric Society, Newark, November 19, on "Surgical Treatment of Athetosis and Paralysis Agitans."—Dr. Waltman Walters, Rochester, Minn., addressed the Essex County Medical Society, Newark, November 14, on "Lesions of the Biliary Tract."

NEW YORK

Course on Diseases of the Chest.—The Rockland County Medical Society is presenting a course on diseases of the chest at the Summit Park Sanatorium, Pomona. The series is as follows:

- Dr. Edgar M. Medlar, Mount McGregor, Pathogenesis of Tuberculosis: Clinical Interpretation, November 15.
- Dr. William J. Ryan, Pomona, Pulmonary Tuberculosis: Early Diagnosis and Differential Diagnosis, November 22.
- Dr. Edward Percy Eglee, New York, Tuberculosis of the Lungs and Pleura; Medical and Surgical Treatment, November 29.
- Dr. Herbert C. Maier, New York, Suppurative Disease of the Lung: Suppurative Pneumonia, Abscess, Bronchiectasis, December 6.
- Dr. Francis B. Berry, New York, Benign and Malignant Neoplasms: Diagnosis, Clinical Effects and Treatment, December 13.
- Dr. Oswald R. Jones, New York, Fibrosis and Emphysema: Causes, Differentiation, Management, December 20.
- Dr. John D. Kernan, New York, Bronchoscopy in Diseases of the Chest, December 27.

The course was arranged by the committee on public health and education of the Medical Society of the State of New York.

New York City

Roentgen Examination for Drafted Men.—The tuberculosis service project of the Works Progress Administration in conjunction with the bureau of tuberculosis of the New York City Department of Health is conducting roentgen examinations of prospective selective service draftees. Mobile x-ray units are set up in four armories to make a film of each man. The films will be developed and read during the period required for the physical examinations. Most of them can be finished within one or two hours. Any men who are found to have evidence of pulmonary disease will be followed up in the routine manner by the health department's bureau of tuberculosis.

Health Preparedness Committee.—Mayor La Guardia has appointed an official Advisory Health Preparedness Committee at the request of Assemblyman Lee B. Mailler, chairman of the New York State Health Commission. The committee has twenty-three physicians, nurses and officials of private and municipal health and welfare organizations.

Among the membership are Drs. John L. Rice, health commissioner, and Willard C. Rappleye, commissioner of hospitals, representing the city; Claude W. Munger, the voluntary hospitals; George Baehr, the New York Academy of Medicine; Condit W. Cutler Jr., Harry P. Mencken, Flushing, Edward R. Cunniffe, Thomas A. McGoldrick, Brooklyn, and Arthur S. Driscoll, Staten Island, the five county medical societies. The committee is intended to function as a unit of the national defense program, operating in the public health field.

National Youth Administration to Examine Youth Employees.—A campaign of preventive medicine is being carried on among National Youth Administration youths between 18 and 24 years of age, consisting of physical tests and laboratory check-ups of the 13,000 National Youth Administration part time workers. The examinations are being conducted by the Medical Unit of the Astoria Work Experience Center, 43-02 Ditmars Boulevard, Astoria, L. I. This is the first time that medical examinations have been given youth employees by a medical unit of the National Youth Administration. In the past they have been conducted with the cooperation of various city hospitals and clinics. The examinations will cover first the youth personnel at the Astoria Center. Afterward those employed in the other centers and agencies will be brought in for tests. The medical unit is under the direction of Dr. Harold Jacobziner, assisted by seven physicians, five dentists, two dental hygienists, two nurses and a laboratory specialist. Persons showing the necessity of further treatment will be referred to the proper clinics. Frequent follow-up tests will be made by the medical unit to determine the progress in each case, and all examinations will be repeated annually. Through the cooperation of the New York City Department of Health, a portable x-ray machine will be provided for chest examinations of those young workers who show a positive reaction to the Mantoux tuberculin skin test. A vigorous campaign of health education will be carried on simultaneously with the medical program. Lectures, movies, dioramas and literature will be used. According to Dr. Jacobziner, the surveys will not show any definite results for some time. They will be carried on over a period of several years so that results may be tested and proved.

NORTH DAKOTA

"North Dakota Naturopathic Physicians, Inc."—Naturopaths must be licensed by a state board to practice in North Dakota, according to a decision handed down by Judge Daniel B. Holt, Fargo. The ruling was made in an action by the state board of medical examiners against "North Dakota Naturopathic Physicians, Inc.," a private corporation incorporated in 1938 for the stated purpose, among other things, of examining naturopaths and certifying as to their qualifications to practice in the state, according to the Grand Forks Herald. The corporation issued certificates to some of its members as "registered naturopathic physicians" and required that these certificates be filed with the register of deeds in the county in which the certificants resided, it was said. Judge Holt, in overruling a demurrer interposed by the corporation, said that, under the pleadings, the naturopaths sought to evade the laws of North Dakota and to do by indirection what they could not do directly, namely to engage in the practice of medicine without a state license. Judge H. A. Bronson, Grand Forks, represented the state board of medical examiners.

OHIO

Cleveland's Health Museum Opened.—The Cleveland Health Museum, first of its kind in the United States, was opened with a ceremony and civic luncheon November 12-13. Dr. James A. Doull, chairman of the advisory council of the museum, presided at the evening meeting. Official greetings were presented from local and national organizations and addresses were delivered by Drs. Howard Lester Taylor, president of the museum, on "From Idea to Museum in Four Years" and Bruno Gebhard, director, on "The Human Estate." Speakers at the luncheon, given by the Cleveland Chamber of Commerce were Mr. F. C. Crawford, president of the chamber of commerce, on "America's First Health Museum—Its Importance to This Community"; Mayor Harold H. Burton, "An Acknowledgement to Those Who Have Made the Museum Possible"; William J. Hutchins, LL.D., president emeritus of Berea College, Berea, Ky., "Health and National Defense," and Dr. William W. Bauer, director of the Bureau of Health Education, American Medical Association, Chicago, "Pictures of Health." The museum had its inception at a meeting of representatives of twenty-three institutions called by the Acad-

emy of Medicine of Cleveland, March 25, 1936. In December 1936 it was announced that Mrs. Francis F. Prentiss was willing to donate her former home at 8811 Euclid Avenue to the cause. During the past four years funds have been accumulated through memberships among the professions and several substantial donations. In May Dr. Gebhard, formerly curator of the Dresden Museum in Germany, was appointed director. During the summer the three story building was remodeled to provide display rooms, offices, workshops and auditorium. The opening display had 133 exhibits, most of which were made in the museum workshops.

OREGON

New Hospitals Opened.—The Blue Mountain General Hospital, a new building with a capacity of twenty beds, was opened at Prairie City in September. Dr. Oliver M. Nisbet, Portland, made an address on the progress of medicine and surgery at the opening ceremony.—A new county hospital and infirmary for Klamath County was dedicated October 13.

Medical Executives' Conference.—The fourth annual meeting of the Pacific States Medical Executives' Conference will be in Portland, December 8. Among subjects to be considered are medical military preparedness, coverage by insurance or other prepayment plans for families of low wage employee groups, the National Physicians' Committee for Extension of Medical Service, federal and state legislation and medical service plans.

Society News.—Speakers before the Multnomah County Medical Society, Portland, November 6, were Drs. Charles E. Gurney, on "Relationship of Plastic Surgery to Tumors of the Face"; William W. Baum, "Some Problems and Activities Confronting the Oregon State Medical Society"; Ralph A. Fenton, "National Problems of the Physician," and John H. Fitzgibbon, "Report of Activities of the House of Delegates of the American Medical Association."

PENNSYLVANIA

Psychiatric Meeting.—Dr. Baldwin L. Keyes, Philadelphia, was chosen president-elect of the Pennsylvania Psychiatric Society at its recent annual meeting in Philadelphia, and Dr. Henry I. Klopff, Allentown, became president. Dr. Leroy M. A. Maeder, Philadelphia, is secretary. Speakers on the program were Drs. Appleton H. Pierce, Coatesville, on "Mental Hygiene"; Samuel B. Hadden, Philadelphia, "Treatment of Neuroses by Class Technic"; Lauren H. Smith, Joseph F. Hughes and Donald W. Hastings, Philadelphia, "First Impressions of Electroshock Treatment in the Psychoses."

Philadelphia

Special Program.—The College of Physicians of Philadelphia presented a special program on medical preparedness, November 8. Francis John W. Roughton, lecturer in physiology at Cambridge University and a member of the British Committee on Blood Storage and Shock, spoke on "Blood Storage and Shock" and Lieut. Col. Arthur P. Hitchens, professor of public health and preventive medicine, University of Pennsylvania School of Medicine, discussed "A Health Program for the Home Side in War Time."

PUERTO RICO

Puerto Rico Medical Association.—The thirty-seventh annual meeting of the Puerto Rico Medical Association will be held in Santurce, December 12-15, under the presidency of Dr. Oscar G. Costa-Mandry, San Juan. Guest speakers will include:

- Dr. Louis F. Bishop, New York, Coronary Disease—Its Diagnosis and Treatment.
- Dr. Malcolm T. MacEachern, Chicago, Trends in Specialization in Medicine.
- Dr. Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, D. C., subject not announced.
- Mr. James A. Hamilton, director of New Haven Hospital, New Haven, Conn., Hospital Administration and the Various Methods of Securing Training.
- Dr. Arthur C. Bachmeyer, Chicago, Relations Between Hospital Administrators and Members of the Professional Staff of the Hospital.
- Mr. Rafael Picó, professor of geography, University of Puerto Rico, The White Man in the Tropics.

Puerto Rican physicians on the program include:

- Dr. Jose C. Ferrer, San Juan, Renal Pain.
- Dr. Jaime F. Pou-Valdejuili, Hato Rey, Pneumothorax in Patients of Middle Age.
- Drs. Ramon M. Suarez and Enrique Koppisch, San Juan, Weil's Disease in Puerto Rico.
- Dr. Ernesto Quintero, San Juan, Control of Venereal Diseases.
- Dr. Rafael Lopez Nussa, San Juan, Treatment of Uterine Cancer.

GENERAL

Deaths from Football Decline.—Eight deaths attributable to football occurred during the first half of this year's season, according to a report by Floyd R. Eastwood, Ph.D., Purdue University, Lafayette, Ind., record keeper for the American Football Coaches and National Collegiate Athletic associations. Five deaths resulted directly from football, two less than in 1939. Two boys died of heart disease and one from an infection. The toll has shown a downward trend since 1937, Dr. Eastwood reported.

Association for Study of Neoplastic Diseases.—The annual meeting of the American Association for the Study of Neoplastic Diseases will be held at Johns Hopkins Hospital, Baltimore, December 19-21. The meeting will consist of demonstrations of microscopic pathology and of roentgenograms and lantern slides. Session topics and chairmen will be:

- Dr. Alexander M. Duff Jr., Baltimore, Lesions of the Nasopharynx, Larynx, Trachea and Upper Respiratory Tract.
- Dr. Leopold Clarence Cohn, Baltimore, Lesions of the Breast.
- Drs. Louise D. Larimore, Greenwich, Conn., and Georgeanna Seegar Jones, Baltimore, Lesions of the Female Genital System.
- Drs. George S. Foster, Manchester, N. H., and William A. Wall, Cortland, N. Y., Lesions of the Endocrine Glands.
- Dr. Howard H. Ashbury, Baltimore, Lesions of Bone.
- Dr. Roscoe W. Teahan, Philadelphia, subject not announced.
- Drs. George A. Stewart and Sam S. Blackman Jr., Baltimore, Lesions of the Lymphoid, Myeloid and Reticulo-Endothelial Systems.

Changes in Status of Licensure.—The Colorado Board of Medical Examiners reports the following action:

- Dr. William Ewell Montgomery, Pueblo, license revoked, October 1, for conviction of a felony.

The Florida State Board of Medical Examiners reports the following action:

- Dr. Eldridge Roy Morlan, Auburndale, license revoked, June 8, for falsifying an affidavit.
- Dr. Scott Robert Edwards, now of New York, license revoked, June 8, for violation of Harrison Narcotic Law.
- Dr. Charles Russell Conway, alias Charles Wade Page, Chipley, license revoked, June 8, because of conviction of stealing an automobile and serving a sentence at the state prison at Raiford.

The Illinois State Department of Registration announces the following action:

- Dr. Archibald B. Calvin, Chicago, license restored, September 23.

The Maine Board of Registration of Medicine announces the following:

- Dr. Henry B. Esmond, Casco, license revoked, July 2, for obtaining fraudulently his license to practice medicine.

The Massachusetts Department of Registration in Medicine announces the following action taken July 11:

- Dr. Anthony Peter Carogana, Chelsea, license revoked for his conviction on charge of performing an abortion.

The South Dakota state board of health and medical examiners announces the following action:

- Dr. George E. Johnson, Gregory, license revoked, July 16, for unprofessional conduct.

Squibb Award in Endocrinology.—To promote interest in research dealing with endocrinology, E. R. Squibb & Sons have established an annual award of \$1,000 to be given through the medium of the Association for the Study of Internal Secretions, according to *Science*. The award will be given to the research worker in the United States or Canada who, in the opinion of the judges, has published during the previous calendar year the most meritorious scientific report dealing with the field of the hormones. While it will be given primarily for publication of specific papers, the judges will be given latitude in the exercise of their function. If in their judgment circumstances and justice dictate, it may be recommended that the prize be divided between two or more persons. It may also be recommended that it be made to a worker for valuable contributions over an extended period, but not necessarily representative of a given year. Membership in the association is not a requisite of eligibility for the award. A committee consisting of five members of the association will be appointed annually by the president to recommend to the council a recipient for the award. Nominations should be sent to the secretary of the association not later than January 15 for presentation at any given spring meeting. All details concerning the nominee will be considered confidential until the announcement is made at the annual dinner, when the award will be presented. While the award is intended as an annual prize, it will be withheld in accordance with the judgment of the awarding committee. In addition to the award provided by E. R. Squibb & Sons, the recipient will be presented with a simple scroll as a memento of the association, the cost to be defrayed by the association.

Nov. 9, 1940.

London Hospitals Carry on During Bombardment

The London hospitals are in the battle zone, nearer to war operations than many a field hospital in past campaigns. Many have suffered severely from bombing and one great hospital of a famous medical school has had to be evacuated, but it carries on. The history of this war will show that in Britain's heroic struggle to save herself and Europe from the new barbarism, none deserve more praise for their work and courage than the hospital staffs—medical, nursing, clerical and domestic. Exposed to bombardment day and night and sometimes even when suffering from it, they carry on not only the usual service for the sick but a well organized system for dealing with the casualties of air raids. There is an elaborate air raid precautions service with a control room and roof watchers. The latter were introduced into factories, so that after an air raid warning work could be carried on until the danger came too near. Facilities are established for carrying on in the subbasements of hospitals when the higher parts become dangerous. Here are beds to which patients in the upper floors can be removed. At nights the subbasement is a sanctuary and haven of rest for those not on duty at the time.

The medical and nursing staffs have to be on the alert every night, for then attacks from the air are much more severe than by day. The casualties are received at a special ambulance entrance and taken to a hall where they are sorted. Persons not severely injured are treated at once; the others are taken to the wards. If the upper floors have been put out of action, an emergency operating room below ground is available.

Following is an example of the courage of our hospital staffs: In southeastern England high explosive bombs cut through the kitchen quarters of a hospital, damaging wards on both sides, killing one nurse, injuring five members of the staff and causing death from shock of several elderly patients. Immediately after the bombing the nurses on duty, medical students and porters set to work to remove the patients from the damaged wards to other parts of the building. They worked while the German bombers were still overhead and splinters from antiaircraft shells were falling. The majority of the nurses were young probationers under the age of 18, who carried on with a coolness and courage to which words cannot do justice.

Casualties from Bombing of the Civilian Population

In the House of Commons Mr. Churchill stated that the Germans claimed that on the night of October 3 they dropped 251 tons of high explosives on London. On that night it took 1 ton to kill three fourths of a person. In the last war the small bombs of earlier pattern which were used killed ten persons for every ton dropped on built-up areas. Therefore the deadliness of the bomb attack on civilians in this war appears to be only one thirteenth of that in the last war. The only explanation was the vastly improved methods of shelter. When we entered this war we expected losses which might amount to 3,000 killed in a single night and 12,000 wounded night after night. We had made hospital arrangements for 250,000 casualties but up to the present as the result of air bombing we had about 8,500 killed and 13,000 wounded. Since the heavy raiding began on September 7 the figures of killed and wounded had declined steadily from over 6,000 in the first week to just under 5,000 in the second, about 4,000 in the third and under 3,000 in the last four weeks. These are casualties—dead and seriously wounded. Mr. Churchill fore-

shadowed new methods of making the wholesale bombing of the civilian population "more exciting to the enemy than it is at present," but of course he would not describe them. "It would be much better for our visitors to find them out for themselves." We must try to have as soon as possible shelters with sleeping bunks for every one in the areas liable to constant attack. Measures were being taken to secure the health of the people under these novel and primordial conditions. The official figures for the casualties in air raids during the month of September are 6,954 civilians killed and 10,615 seriously injured.

The National Health Improves Under War Conditions

In the House of Commons the Minister of Health, Mr. Malcolm MacDonald, gave a survey of the health of the nation under war conditions. He deprecated the superficial view that health services were a prime concern in peace but in war were of secondary importance, while energy was concentrated on the production of munitions. But at the machines stood hosts of men and women whose health was of crucial importance. The health of the nation was on the march and not even the calamity of war could stay it. The health statistics for 1939, in which there were eight months of uneasy peace and four months of war, were almost uniformly better than those of the preceding year, which in turn were an advance. In 1939 50 per thousand children born died before their first birthday. That was the lowest figure ever recorded and was 3 per thousand less than in 1938. It was less than half the figure for 1914, the first year of the first world war. The second significant index was the maternal mortality. This fell to 2.82 per thousand births in 1939, which was also the lowest figure ever recorded in the country and was 0.15 below the previous year and little more than two thirds of the figure for 1914. The death rate for tuberculosis did not show any decline, but the figure was encouraging. The crude death rate in 1939 from all forms of tuberculosis was 636 per million living. That was 1 per million higher than in 1938 but less than half the figure for 1914. Only one case of smallpox was notified in 1939, the figures for scarlet fever and diphtheria were lower than those of 1938, and the anticipated biennial measles epidemic failed to appear. But our health chart was not uniformly good. There was an ominous increase in the incidence of cerebrospinal fever. The disease, however, was less formidable, thanks to sulfapyridine, which had reduced the mortality by almost two thirds.

American Vans for Blood Transfusion

The Medical Research Council has received four motor vehicles equipped for medical work from the United States. They were originally purchased by the American Quakers and the International Commission for the Assistance of Child Refugees for use in France. They will now be used principally for the work of the Emergency Blood Supply depots in the neighborhood of London.

Marriages

BARCLAY MILLER BRANDMILLER, Youngstown, Ohio, to Miss Jean Elizabeth Richards in Struthers, September 19.

ROLAND SIGURD ARONSON, Philadelphia, to Miss Catherine Reimann Roess of Oil City, Pa., August 31.

EMORY HAMLIN ANDERSON, Paia, Hawaii, to Miss Janice Watkins of Oakland, Calif., August 21.

MAURICE MILTON FLIESS, Clifton Forge, Va., to Miss Irwin Rand Foster of Lynchburg, August 3.

JOSEPH NEGLEY SCHAEFFER, Dayton, Ohio, to Miss Sarah Jane Bradshaw of Bexley in August.

BEN E. EWING to Miss Mary Kline, both of Madison, Neb., June 26.

Dèaths

Oliver Thomas Osborne ☉ New Haven, Conn.; Yale University School of Medicine, 1884; member of the House of Delegates of the American Medical Association in 1902, 1903 and 1908 and member of the Council on Pharmacy and Chemistry from 1910 to 1916; vice president from 1910 to 1920, and delegate to the United States Pharmacopoeial Convention and member of the revision committee; president of the New Haven County Medical Association in 1899 and the American Therapeutic Society in 1905; fellow of the American College of Physicians; instructor of materia medica and therapeutics, 1891-1892, assistant professor of materia medica and therapeutics from 1892 to 1895, professor of materia medica and therapeutics from 1895 to 1906, professor of materia medica and therapeutics and clinical professor of medicine from 1906 to 1911, professor of therapeutics from 1911 to 1922, clinical professor of therapeutics from 1922 to 1925 and since 1925 clinical professor emeritus at his alma mater; one of the founders and chairman of the medical board of the Gaylord Farm Sanatorium, Wallingford, Conn., from 1903 to 1940; received the first Chompret Prize of the International Academy of Stomatology, in cooperation with the American Society of Stomatologists in 1933; editor of the "Section on Therapeutics" of *THE JOURNAL* from 1907 to 1919; author of "Introduction to Materia Medica and Pharmacology," 1906; co-author with Dr. Morris Fishbein of "Handbook of Therapy," 1910, ninth edition 1933; author of "Prevention and Treatment of Infections," 1915, "Disturbances of the Heart," 1916, third edition 1925, "Disturbances of the Kidneys," 1917, "Principles of Therapeutics," 1921, "What Everyone Ought to Know," 1929, "Mouth Infection," 1934, and "The Evaluation of Symptoms," 1935; section on "Acromegaly" in Buck's "Reference Handbook of the Medical Sciences," 1893, and "Organotherapy" in Cohen's "System of Physiologic Therapeutics," 1905, and more than 100 articles in medical periodicals; aged 77; died, November 11.

William Gooderham Cameron, Tacoma, Wash.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the Washington State Medical Association, American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; past president of the Pierce County Medical Society and the Puget Sound Academy of Ophthalmology; formerly member of the state legislature; at one time health officer of the village of Staples, Minn.; ophthalmologist and otolaryngologist, Northern Pacific, Tacoma General and St. Joseph's hospitals; editor of the *Bulletin of the Pierce County Medical Society*; aged 66; died, October 23, of coronary occlusion.

George Mason Magruder ☉ Senior Surgeon, United States Public Health Service, Shadwell, Va.; University of Virginia Department of Medicine, Charlottesville, 1884; was commissioned an assistant surgeon in the United States Marine Hospital, later known as the United States Public Health Service, April 24, 1886, promoted to passed assistant surgeon Aug. 4, 1890, to surgeon Aug. 5, 1899, to senior surgeon Aug. 11, 1917, and retired Aug. 13, 1927; aged 77; died, October 10, in the University of Virginia Hospital, Charlottesville, of acute myelogenous leukemia.

Robert George Cook ☉ Canandaigua, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1889; member of the American Psychiatric Association; at various times neurologist, St. Mary's Hospital, Rochester, attending neurologist, Rochester City Hospital, consulting neurologist, Rochester State Hospital, director of the Frederick Ferris Thompson Memorial Hospital; consulting physician and treasurer and formerly physician in charge of the Brigham Hall Hospital; aged 76; died, October 25, of coronary occlusion.

Paul Tonnel Dessez ☉ Medical Inspector Commander, United States Navy, retired, Waterford, Conn.; Georgetown University School of Medicine, Washington, D. C., 1897; was commissioned an assistant surgeon in the navy June 20, 1903; veteran of the Spanish-American and World wars; was retired for disability on Dec. 1, 1922; received the Distinguished Service Medal, the Navy Cross, the Croix de Guerre and the Purple Heart; fellow of the American College of Surgeons; aged 64; died, August 29.

George Michael Jennings ☉ Missoula, Mont.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; past president of the Medical Association of Montana and of the Montana State Board of Health; member and past president of the state board of medical examiners; fellow of the

American College of Surgeons; chief surgeon of the Northern Pacific Beneficial Association Hospital; on the staff of St. Patrick Hospital; aged 60; died, October 14.

Henry Jackson, Brookline, Mass.; Harvard Medical School, Boston, 1884; member of the Massachusetts Medical Society and the Association of American Physicians; formerly instructor in clinical medicine at his alma mater; for many years on the staff of the Boston City Hospital; aged 81; died, October 4, of coronary thrombosis.

Charles Edward Boynton Jr. ☉ Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1931; on the staff of the Crawford W. Long Hospital; aged 39; died, September 25, of estivo-autumnal malaria and chronic amebiasis.

Charles Miller Glassmire, Philadelphia; Medico-Chirurgical College of Philadelphia, 1914; on the staff of the American Hospital for Diseases of the Stomach; aged 53; died, October 7, of coronary thrombosis and angina pectoris.

William T. Highberger, Maysville, W. Va.; University of Maryland School of Medicine, Baltimore, 1883; member of the West Virginia State Medical Association; aged 80; died, September 6, of hemiplegia and arteriosclerosis.

Mary Margaret Johnson, Spokane, Wash.; Cleveland Homeopathic Medical College, 1898; member of the Washington State Medical Association; aged 76; died, October 20, in Summer of cardiorenal vascular disease.

Hugo Emil Nelson, Sharon Springs, Kan.; John A. Creighton Medical College, Omaha, 1902; member of the Kansas Medical Society; aged 69; died, September 2, in the Mercy Hospital, Denver, of carcinoma of the prostate.

Newton Howard Jenkins, Kingston, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1905; aged 57; died, October 5, in the Robert Packer Hospital, Sayre, of polycystic kidney and heart disease.

Arthur Burnham Johnson, Toledo, Ohio; Rush Medical College, Chicago, 1928; for many years on the staff of the Women's and Children's Hospital; aged 43; died, October 3, of injuries received in a fall.

Cecil Norbert Brady, Newton, Mass.; Tufts College Medical School, Boston, 1913; served during the World War; aged 53; died, October 23, in the United States Naval Hospital, Chelsea, of heart disease.

Willis Sylvester Cobb, Corning, N. Y.; Albany Medical College, 1890; for many years county coroner; aged 78; died, October 5, in the Veterans Administration Facility, Bath, of coronary heart disease.

Lloyd Ephraim Strohm, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1916; aged 57; died, September 28, at Audubon, N. J., of acute cardiac dilatation and myocarditis.

Stephen Shaffer Landis ☉ Harrisburg, Pa.; University of Pittsburgh School of Medicine, 1911; for many years member of the school board; aged 53; died, October 1, of coronary occlusion.

William Edward Barton, Bethalto, Ill.; Barnes Medical College, St. Louis, 1909; formerly health officer of Wood River; aged 60; died, October 15, in Roxana of carcinoma of the stomach.

Anita Newcomb McGee, Washington, D. C.; Columbian University Medical Department, Washington, 1892; aged 76; died, October 5, of arteriosclerosis and cerebral hemorrhage.

Carl V. Cruse, Iola, Ill.; Barnes Medical College, St. Louis, 1899; member of the Illinois State Medical Society; aged 67; died, October 12, of cardiorenal disease and arteriosclerosis.

Avington Adam Edgington, Omaha; State University of Iowa College of Medicine, Iowa City, 1897; aged 75; died, October 3, of paralysis agitans and hypostatic pneumonia.

Randolph Brunson, West Orange, N. J.; Medical Department of Tulane University of Louisiana, New Orleans, 1888; aged 75; died, September 25, of cerebral hemorrhage.

James F. Gullett, Hot Springs National Park, Ark. (licensed in Arkansas in 1903); aged 76; died, October 1, in St. Joseph's Hospital of bronchopneumonia.

Elliott H. Burnett, Rockford, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1893; aged 85; died, October 1, of bronchopneumonia.

John M. Howard ☉ Amesville, Ohio; Starling Medical College, Columbus, 1895; aged 77; died, October 10, of injuries received in an automobile accident.

Hiram A. Castleberry, Ben Wheeler, Texas; University of Louisville (Ky.) Medical Department, 1895; aged 78; died, October 14, of gastric carcinoma.

Correspondence

DRUGS IN GREAT BRITAIN

To the Editor:—A note in *Science* of October 25, page 373, calls attention to the fact that important changes in medical prescribing in Great Britain are recommended by an official medical committee. Among the drugs said to be "in frequent use" and which are now hard to obtain are balsam of tolu, buchu leaves, calumba root, black catechu, gelsemium root, jalap and seneca root. Why these and many other antique galenicals and proprietary remedies are still used by British physicians is difficult to understand unless it is on the basis of steadfast British tradition. If the present war has no other good effect, it may at least serve to renovate some time worn habits in British therapeutics.

HOBART A. REIMANN, M.D., Philadelphia.

NOTE.—The *Epitome of the Pharmacopeia and National Formulary*, 1940 edition, published under the authorization of the Council on Pharmacy and Chemistry of the American Medical Association, makes the following succinct comments concerning these substances:

Balsam of Tolu. Used chiefly in the form of the syrup, which is little more than a pleasantly flavored vehicle.

Buchu. At one time largely used as a diuretic, especially in catarrhal cystitis. Value doubtful.

Calumba. Used as a simple bitter and stomachic. It appears to have no advantage over other bitters, such as gentian, except that it is free from tannin.

Gambir (Pale Catechu). Astringent; used against diarrhea in form of tincture.

Gelsemium. Used in migraine and neuralgia, and in the treatment of rheumatic, or ovarian and uterine pain. Efficacy uncertain. Untoward symptoms sometimes result from comparatively small doses.

Jalap. Drastic hydragogue cathartic, used especially in dropsies.

Seneca snake root. Employed as a nauseant expectorant (by virtue of the irritant saponin).

None of the foregoing are described in the U. S. Pharmacopeia, nor are the preparations accepted for inclusion in N. N. R.; they are not mentioned in *Useful Drugs*. They belong to those listings of drugs which are in the twilight of their existence.

The point raised by Dr. Reimann is well taken. It may be, however, that our English friends are more accustomed to the use of these drugs and therefore the lack of them may mean a hardship to those so accustomed.—En.

MEN NURSES SUGGESTED FOR AMBULANCE DUTY

To the Editor:—In THE JOURNAL November 2 under Current Comment the questionable shortage of interns is discussed, and reference is made to the amount of time that the intern has to spend on ambulance duty. It was suggested that nurses or orderlies might be assigned to the more routine ambulance duties, such as transfer of patients.

In New York City two of the public hospitals have men nurses on the psychiatric ambulances. For the record I will say that in New York State, at least, men nurses are readily available, have had sound courses of training in medical, surgical, urologic and psychiatric nursing and are duly examined by the Bureau of Nurse Examiners and licensed by the University of the State of New York.

As secretary of the Men Nurses Section of the New York State Nurses Association and chairman of the program committee of the Men Nurses Section of the American Nurses Association, I would greatly appreciate any publicity or notice which your publication would give to the use of men nurses on ambulance duty. The man nurse is physically suited to the duty, and his professional training has prepared him to accept responsibility and to use judgment. While the salary of the man nurse

is from \$105 to \$135 a month, he would release the interns for the duties which they expect.

The Men Nurses Section of the American Nurses Association has available considerable information on the national distribution of men nurses which it would gladly furnish to any employers who are seeking men nurses for this work.

NATHANIEL H. WOODING, R.N., Brooklyn.
Secretary, Men Nurses Section, New
York State Nurses Association.

TRIBUTE TO PROFESSOR WENCKEBACH

To the Editor:—With the sad announcement of the death of Prof. Karel F. Wenckebach in Vienna recently there comes to a dramatic close one of the most brilliant epochs of contemporary medicine. His passing will bring sorrow to hundreds of American physicians who enjoyed the rare privilege of basking in the warm friendship of the great group of medical scientists who made Vienna during the nineteen twenties the shrine of post-graduate teaching.

It was here at the Wenckebach Clinic that modern cardiology was born; one by one the great lights of pioneer medical thought have gone out, and all the illustrious figures who strode across the stage of the clinic platform have disappeared. Through the doors of the American Medical Association of Vienna many doctors made lasting friendships with these teachers, and all of us will recall for a long time to come the pleasant memories of this group with their special little eccentricities:

Wenckebach himself, of military mien, a little out of place, perhaps, in the gemütlich atmosphere of Vienna, stern, dogmatic but kindly and a true clinician. To him angina pectoris was not a disease entity but only a symptom and until the death of Mackenzie was the latter's chief antagonist.

Heinrich Winterberg, quiet, calm, studious, the liaison member between the clinician Wenckebach and the laboratory experts. The clinical interpreter of the science of electrocardiography and the defender of Waller, the "forgotten man" of English cardiology.

Charles F. Rothberger, hard of hearing, the technical expert of the laboratory and the originator of experimental animal research in the understanding of electrocardiography, eager, enthusiastic, a brilliant mathematician and inventor of complicated apparatus in the study of electrodynamic phenomena of the beating heart.

Jacob Pal, elder physician of the group interested in the physiology of the circulation, classifier of diseases of the arteries, inventor of the modern blood pressure apparatus, exponent of arteriosclerosis.

Rudolph Kaufmann, the American postgraduate student's personal physician, exponent of the great family doctor. A cardiologist of many specialties, brilliant diagnostician.

Theodore Meyer, pharmacologist, research worker in glyceryl trinitrate, who developed the theophylline compounds, now called aminophylline, for the relief of stenocardial symptoms, early assayer of digitalis, biochemist largely responsible for the development of the mercurial diuretics, a charming personality.

Jacob Erdheim, pathologist extraordinary, the lordly clinical ruler of the postmortem table, at whose feet sat hundreds of enthralled American students who saw dead organs alive again and the heart reliving its last episode.

Wilhelm Neumann, the thoracic clinician to whom the sounds of the heart and lungs spoke in unmistakable terms, exponent of the phonetic method of teaching and demonstrator of many physical signs in the chest.

Finally, Julius Wagner-Jauregg, dean, stern, a strict disciplinarian albeit a kindly man, perpetually astonished at the ingenuity of American excuses, sincere advocate of academic freedom for medical research, later Nobel prize winner in medi-

cine. Anticipated instinctively, perhaps, the fate of Austria and sincerely believed that the torch of scientific medicine would eventually burn brightest in the United States.

And now the school is closed; the doors are shut and the last light has gone out. All those of us privileged to have known these men will cherish the memory of the Viennese school of medical leadership which flourished from 1920 until about 1928, and to every one who knew him the passing of the chief himself, Wenckebach, must call forth wistful thoughts of a medical era now definitely gone.

ALBERT S. HYMAN, M.D., New York.

President, Alumni Society of the American
Medical Association of Vienna.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

NICOTINIC ACID FOR TOXIC MANIFESTATIONS OF SULFANILAMIDE

To the Editor:—In *The Journal* for March 2, 1940, page 756, Dr. Doughty reported the successful treatment of certain toxic manifestations of sulfanilamide with nicotinic acid. A pharmaceutical house has asked if there is sufficient evidence to warrant the inclusion of nicotinic acid in a tablet of sulfanilamide. As this is not mentioned in the recent paper by Dr. Long, I am wondering whether such a combination would be justifiable?

M.D., Canada.

ANSWER.—The available data concerning the use of nicotinic acid in preventing the toxic manifestations which may arise in the course of sulfonamide therapy are contradictory. Certain observers have reported that large doses of nicotinic acid (from 200 to 400 mg. a day) will decrease nausea and vomiting, cyanosis and other toxic manifestations of sulfanilamide therapy. Since McGinty's original report on this subject (McGinty, A. P.; Lewis, G. T., and Holtzclaw, M. R.: *J. M. A. Georgia* 28:54 [Feb.] 1939), an attempt has been made in the Johns Hopkins Hospital to evaluate nicotinic acid in the prevention of the toxic manifestations which arise in the course of therapy with sulfanilamide and its derivatives. In certain cases it has seemed that the administration of nicotinic acid decreased nausea and vomiting, cyanosis, and the like, while in other cases treatment with nicotinic acid has had absolutely no effect on the toxic reactions of sulfanilamide. Because completely satisfactory methods of evaluating nicotinic acid deficiency states in human beings are not available, it has been impossible to determine whether the apparent good results from combined therapy in certain cases resulted from the abolishment of a deficiency state. At the present time the proposed combination of nicotinic acid with sulfanilamide in tablet form would not appear to be based on sound clinical observations.

HYPOGONADISM IN BOY

To the Editor:—What is the present treatment of hypogonadism in a youth 17 years old who is in perfect health and mentally alert and who shows absolutely no evidence of secondary sex characteristics? Will you please discuss the probability of improvement and the likelihood of permanence of results?

L. C. Howe, M.D., Muscatine, Iowa.

ANSWER.—It is assumed that gross pituitary disease has been ruled out as far as possible by x-ray examinations of the skull and visual fields. This step is necessary whether the patient has suggestive complaints or not. The essential defect may lie in the pituitary body or in the testes. Large amounts of follicle stimulating material may be found in the urine if the defect is gonadal, but the techniques for its best measurement are as yet not agreed on and are not available for those without the services of a research laboratory. The results of treatment may answer this question. Pregnancy urine extract 500 international units three times weekly may be administered for a period of from four to six months, the results judged by a photographic record of progress. This dose should be achieved by graded steps and may even be doubled if well tolerated. If the response is satisfactory, treatment should be continued; if none is secured, the

testes must be regarded as refractory and androgens used. Testosterone propionate 25 mg. intramuscularly three times weekly will usually produce unmistakable results in from three to four months or less. Androgenic and gonadotropic therapy are substitutional and regression of sex development may be expected if the patient is eunuchoid or suffers from pituitary dysfunction. This may be a case of delayed puberty in which the prognosis for normal sexual development is good.

FORMALDEHYDE POISONING

To the Editor:—I should like to know the possible symptoms and signs found in people working with formaldehyde. A patient complains of weakness, dizziness and tingling of the fingers and nervousness and loss of weight. Physical examination gives negative results. Urinalysis is negative. The electrocardiogram is essentially normal. Blood examination reveals erythrocytes 4,710,000, hemoglobin 14 Gm., color index 0.96, leukocytes 8,800. The differential count is essentially normal.

Earl Herron, M.D., Chicago.

ANSWER.—The characteristic manifestations of industrial formaldehyde poisoning are conjunctivitis, coryza, bronchitis, dermatitis, increased sensitivity of the skin in the absence of dermatitis, dizziness and feeling of great weakness. These symptoms appear in mild acute cases resulting from inhalation of the formaldehyde gas and in the case of cutaneous lesions direct contact with formaldehyde in solution. More prolonged involvement intensifies these lesions and in addition there may appear the symptoms of kidney irritation such as anuria, softened, necrotic fingernails, gastro-enteritis, rarely bronchopneumonia, hepatitis, anorexia, sleeplessness and palpitation.

The symptoms mentioned are compatible with the diagnosis of formaldehyde injury, but one could expect concomitant signs of irritation of the eyes, the upper and lower respiratory tract or the skin.

NAUSEA AND VOMITING FROM GENTIAN VIOLET PILLS

To the Editor:—I am treating a family infected with pinworms—*Oxyuris vermicularis*—with gentian violet pills, according to the routine described in *The Journal*, June 8, 1940. I find nausea and vomiting so severe that carrying out the routine is impossible. Is there a way of overcoming this?

M.D., Connecticut.

ANSWER.—Nausea and vomiting and even diarrhea may occur during the oral administration of gentian violet. These symptoms quickly subside on withdrawal of the drug.

The use of a coated tablet that does not disintegrate in the stomach is advised since not only is less gastrointestinal irritation produced but the effectiveness against oxyuriasis is enhanced. The diet should contain a moderate amount of roughage, fatty foods should be avoided and alcohol should be interdicted. It may be necessary to reduce the dosage or even to stop the drug for from twenty-four to forty-eight hours and continue the treatment with the maximum dose that is tolerated without unpleasant symptoms. In these instances it is recommended that the period of treatment be extended so that the total calculated dose is taken. Small doses of bismuth subnitrate may aid in allaying gastrointestinal symptoms.

PROPHYLACTIC VACCINATION FOR UNDULANT FEVER

To the Editor:—There have been a number of scattered cases of abortus fever among cows in this region; there have also been occasional cases of human infection. Veterinary men "vaccinate" cows against this. The situation is better now. We medical men use the vaccine for therapeutic purposes when needful. I have seen no reports in *The Journal* of the use of vaccine for prophylactic purposes and write to inquire: In the presence of an endemic or partial epidemic situation, when individuals have used milk from infected cows without pasteurization (and without boiling) what doses of the vaccine should be given? How long does it take for immunity to be thus established? How often or at what intervals should the doses be given and should such doses be graduated upward progressively? Is it possible to obtain immunity by any means before the end of the incubation period of the trouble is reached in man? Are there any antitoxins known or on the market? If a family has been continuously using the milk from a cow now suspected to have had the trouble for one and one-half years past have they probably not developed a certain amount of immunity? Can an intensive short course of vaccination be put in operation by using short intervals between injections? I have used with success the combination of sulfanilamide and vaccine.

Matthew Karasek, M.D., Shidler, Okla.

ANSWER.—Prophylactic vaccination of human beings against *Brucella* infection has not been studied on a scale sufficient to demonstrate its value. The fact that serum agglutinins may appear in relatively high titer following a cutaneous test with diluted *Brucella* vaccine or brucellergin in presumably normal individuals points to the possibility that protection might be afforded by vaccination. There is need for controlled studies in this field.

QUERIES AND MINOR NOTES

Jour. A. M. A.
Dec. 7, 1940

POLYNEURITIS OF PREGNANCY

To the Editor:—Is there evidence to show that parenteral administration of thiamine or liver extract would be more effective than oral administration? What would be considered effective treatment for a case of polyneuritis of pregnancy? How long should intensive vitamin therapy be continued before abandoning it as ineffective? The patient in question is a well nourished woman with myopia. The stated age is 36, the apparent age 50 years. There have been grand mal seizures since chorea at about 11 years. They have been controlled the past three years with phenobarbital 0.1 Gm. daily. She is a septipara, entirely normal except for the last recent gestation, which began with severe vomiting, dyspnea on slight exertion and irregular pulse. Although I feared for her life, she easily delivered a 9 pound (4,000 Gm.) infant, after which a moderate edema rapidly cleared away. For the past two years she has had rather severe left sciatic neuritis, in the hope of curing which all teeth were futilely removed. After delivery this pain was still annoying her but in addition she complained of numbness and tingling of both legs, more on the left. The proprioceptive sense in the feet and toes has decreased but is not gone. The knee jerks were exaggerated about the tenth postpartum day but now two months later they are only faintly active. Now (two months post partum) Romberg's sign is negative. The finger to nose test is normal on both sides. There is staggering gait, which is seemingly due to weakness. She turns her ankles frequently. The pupils react sluggishly to light. Her tongue is covered with short fur, is smooth on the edges and has been subject to soreness several times in the past two months. Two weeks after delivery free hydrochloric acid was present in the stomach produced by alcohol stimulation but is produced by histamine injection, to which she had a severe general reaction. The red blood count is 4,700,000, the hemoglobin 104 per cent, Sahli. The spinal fluid is normal and under low pressure. The Kahn reaction is negative. She has been taking about 2.25 Gm. of dried brewer's yeast daily for six or eight weeks but no distinct improvement has occurred. She has had a small amount of liver. Phenobarbital was discontinued for a month for fear it might have been a contributing factor, but because of recurrence of epileptic seizures it has been resumed.

ANSWER.—There is considerable clinical and experimental evidence to show that parenteral administration of either thiamine hydrochloride or liver extract is far superior to that of oral administration. The oral administration carries with it a questionable amount of absorption. In a 3,600 bed charitable hospital vitamin B₁ and liver are given parenterally. The following is suggested as an effective therapy for a case of polyneuritis of pregnancy: 3,000 units of vitamin B₁ or thiamine hydrochloride or vitamin B complex daily hypodermically for a period of from twenty-one to thirty days; a diet rich in vitamin B content such as yeast, liver, whole wheat bread, cereals, eggs, nuts, lean pork, milk, vegetables and rice polishes; nicotinic acid (vitamin B₂) in doses of 50 mg. ten times a day for three weeks and possibly for four before concluding that it is ineffective. From the evidence submitted in this case one should be suspicious of a subacute combined degeneration of the spinal cord related to either avitaminosis or pernicious anemia.

Theodore E. Wade, M.D., Pueblo, Colo.

NO ARTERIES EXEMPT FROM ATHEROSCLEROSIS

To the Editor:—Do you know of any artery or groups of arteries in which intimal thickening, atherosclerosis or medial sclerosis never develops? In other words, are there any arteries in the body in which the lumen always remains of the same caliber and the walls remain free of destructive processes throughout life?

ANSWER.—There is no artery which is always free from pathologic changes during a long life, although occasionally essentially normal coronary arteries are found in persons 60 years of age. Cerebral arteries are usually attacked late in life. Paradoxically the main renal arteries show less atherosclerosis than the other abdominal branches of the aorta. Lesions extending from the orifices for a short distance are common. Great hypertrophy of the media may occur with hypertension, but up to the division of the vessel there is frequently no atherosclerosis.

Roy J. Popkin, M.D., Los Angeles.

SOAP SUBSTITUTES FOR SENSITIVE SKIN

To the Editor:—A patient develops an allergic response to every form of soap used. Can you suggest to me some substitute for soap?

ANSWER.—Sensitivity of the skin to soap may be either non-specific or specific. Nonspecific dermatitis is due to the lack of tolerance to the alkali content of most soaps. It is characteristic of highly irritable skin that its tolerance for alkali is low. For this reason most dermatologists forbid the use of soap (everywhere except on the scalp) in cases of eczema. Specific sensitivity to soap may be due to dyes, perfumes and other extraneous ingredients, rather than the salts of the fatty acids, which are the components of soaps. Among the ingredients to which specific sensitivity is to be considered are cottonseed oil and flaxseed oil in persons sensitive to these substances.

Milton H. Erickson, M.D., Eloise, Mich.

Soap substitutes that are frequently used are oils, as liquid petrolatum, sesame oil and various vegetable oils. Each of these should be tried in turn for the patient's tolerance to it. Another group of substances used as soap substitutes are the various sulfonated oils available commercially. They have a drying effect on the skin and may require the use of a small amount of oil afterward to counteract this effect. It should be determined that the oil used is nonirritating to the individual patient.

SYPHILIS OF MOTHER, NURSING AND CONTINUED TREATMENT

To the Editor:—A woman in the fourth month of pregnancy is discovered to have positive tests for syphilis. No signs or symptoms of activity are present and the date of infection is unknown. Intensive continuous treatment was carried out to the time of delivery of a full term normal baby. The mother's tests have been persistently positive. Assuming for the sake of argument that her disease is truly latent, that her treatment was adequate by all standards and that the baby is nonsyphilitic, (1) May the mother nurse the baby? (2) May the mother have a postpartum rest period or a rest at any time during nursing?

ANSWER.—1. The mother may nurse the baby. 2. For her own sake the mother would require more treatment than one supposes her to have had on the basis of the information supplied, and treatment therefore should be continued. If, however, she has been adequately treated for her own sake, further treatment is not necessary simply because she is nursing the baby.

M.D., Illinois.

POLYCYTHAEMIA VERA

To the Editor:—I am a victim of polycythaemia vera. Please inform me regarding the technic that I should use on myself with a simplex Westinghouse x-ray machine of 50 milliamperes and 85 kilowatts in treatment for this condition. If my blood count is 7,000,000, just what technic should I use.

ANSWER.—Most internists and hematologists agree that polycythaemia vera is best treated by venesection. Irradiation may be tried. One hundred roentgens is given over the spleen three times a week for two weeks. Further irradiation must depend on the blood count.

M.D., Idaho.

FREQUENT MENSTRUATION AND ENLARGED THYROID IN YOUNG GIRL

To the Editor:—A girl aged 15 menstruates every two to three weeks and has a noticeable enlargement of the thyroid. She is entirely normal otherwise. In seeking authoritative opinions I have received conflicting advice. On the one hand it was suggested that she be given antithyroid-5 and that the administration of thyroid in adolescent goiter is often of aid with increased thyroid activity and the frequent menstrual periods is contraindication to any type of estrogenic therapy, the preparation of choice being corpus luteum.

ANSWER.—There is no connection between the enlargement of the thyroid and the frequent menstruation. The only treatment indicated in such cases is a small dose of iodine (about 10 mg. of potassium iodide a week) to prevent further enlargement of her thyroid. No attempt should be made to influence ovarian function at this age, because some spontaneous adjustment may occur soon. Moreover, the frequency of menstruation shows a considerable amount of normal variation.

M.D., Wisconsin

TYPHUS VACCINES

To the Editor:—In Queries and Minor Notes (The Journal, Oct. 5, 1940, p. 1218) in answer to an inquiry about typhus vaccines and serums it was stated that up to the present time typhus vaccines are still in the experimental stage. Two vaccines seem to have outgrown the experimental stage and are successfully employed in routine vaccinations: 1. Weigl vaccine (Professor Weigl, director of the Polish Institute at Lodz) is considered the most effective vaccine made from the intestine of lice which have been infected with *Rickettsia prowazekii*. 2. The Weigl vaccine (Dr. Rudolf Weigl, author of the chapter on the typhus fever group, Handbook of Virus Diseases, 1939, vol. 2, p. 528; Arb. Inst. 122: 220, 1939) does not use the classic *Rickettsia prowazekii* but Rickettsia mooseri, the virus of the murine typhus, and Weigl prefers Cox's method (chicken embryo, vitelline sac inoculation, Pub. Health Rep. 53: 2241 [Dec. 23] 1938). Weigl was making vaccine on a larger scale for the Polish campaign of the German army last fall and winter. Statistical data relating thereto could not yet be obtained. Latest reports refer to the discovery of a specific toxin, probably an endotoxin (Gildemeister and Haagen). This *Rickettsia* toxin is not more resistant than the virus itself and can be destroyed by formaldehyde, heating to 60 C. or storage for seven days. In mouse experiments typhus serums neutralized the specific toxin and thus prevented the occurrence of the typical exanthem as well as circulatory and nervous symptoms while they prevented incubation of infection only in single cases.

F. O. W. Voigt, M.D., Oskaloosa, Iowa.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, November 30, page 1910.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: * Phoenix, Jan. 7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, Dec. 11. Written. Los Angeles, Feb. 24-27. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: * Denver, Jan. 7-10. Applications must be on file not later than Dec. 23. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

GEORGIA: Atlanta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 8-11. Sec., Dr. James A. Morgan, 48 Young Building, Honolulu.

IDAH0: Boise, April 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 335 State Capitol Bldg., Boise.

ILLINOIS: Written. Chicago, Jan. 21-22. Reciprocity. Chicago, Jan. 23. Supt. of Registration, Dept. of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Bldg., Fort Wayne.

IOWA: Des Moines, Dec. 9-11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 10-11. Sec., Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

MARYLAND: Regular. Baltimore, Dec. 10-13. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homoeopathic. Baltimore, Dec. 10-11. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: * Ann Arbor and Detroit, June 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, Jan. 21-23. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Reciprocity. Helena, March 31. Written. Helena, April 1. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEVADA: Reciprocity with oral examination, Feb. 3. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 13-14. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 14-15. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 27-30. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH CAROLINA: Reciprocity. Durham, Dec. 10. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 413 S. Third St., Grand Forks.

OHIO: Columbus, Dec. 9-12. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, Dec. 11. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: * Portland, Jan. 14-16. Exec. Sec., Miss Lorienne M. Conlee, 603 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, January 7-11. Acting Sec., Bureau of Professional Licensing, Miss Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, Jan. 2-3. Sec., Division of Examiners, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: * Pierre, Jan. 21-22. Dir., Medical Licensure, Dr. J. E. D. Cook, Pierre.

TENNESSEE: Memphis, Dec. 18-19. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: Seattle, Jan. 13-15. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WISCONSIN: * Madison, Jan. 14-16. Applications must be on file not later than Jan. 2. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Feb. 3-4. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, Dec. 17. Sec., Dr. Robert L. Nugent, University of Arizona, Science Hall, Tucson.

COLORADO: Denver, Dec. 9-10. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Feb. 8. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, April 21-22. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

IOWA: Des Moines, Jan. 14. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor, Detroit and East Lansing, Feb. 14-15. Sec., Miss Flora E. Dube, East Lansing.

MINNESOTA: Minneapolis, Jan. 7-8. Sec., Dr. J. Charnley McKinley, University of Minnesota, 126 Millard Hall, Minneapolis.

NEBRASKA: Omaha, Jan. 14-15. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Feb. 15. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH DAKOTA: Endorsement. Yankton, Dec. 21. Sec., Dr. Gregg M. Evans, Yankton.

WASHINGTON: Seattle, Jan. 9-10. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

Idaho April Report

Mr. H. B. Whittlesey, director, Bureau of Occupational Licenses, reports the written examination for medical licensure held at Boise, April 2-6, 1940. The examination covered twenty-one subjects and included 140 questions. An average of 75 per cent was required to pass. Twenty-three candidates were examined, twenty-two of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1937)	79,	81.5
Loyola University School of Medicine.....	(1940)	85	
Northwestern University Medical School.....	(1928)	81,

Book Notices

The Emperor's Itch: The Legend Concerning Napoleon's Affliction with Scabies. By Reuben Friedman, M.D., Assistant Professor of Dermatology and Syphilology, Temple University School of Medicine, Philadelphia. Cloth. Price, \$1.50. Pp. 82, with 10 illustrations. New York: Froben Press, 1940.

It is said that 40,000 books have been written on the life of Napoleon, but the present interesting monograph by Friedman is the first which discusses an annoying disease of the skin from which he suffered for many years. This phase of Napoleon's life has either been overlooked or been misunderstood by previous biographers.

The story that the disease of the skin from which Napoleon suffered was scabies is shown by the author to be a myth. There are no authentic records to prove that he ever had this disease. In view of the emperor's cleanly habits and the long duration of the disorder and because of the numerous sulfur baths which he took, it seems impossible that the disease could have been scabies. Furthermore, the Empress Josephine is not known to have suffered from scabies, although Napoleon's second wife, Marie Louise, is said to have been affected. However, it has been stated that she was somewhat promiscuous sexually. Finally, the remedy which his physician Corvisart used successfully was an extremely weak and practically useless one for the treatment of scabies.

The author suggests with good reason that Napoleon actually suffered from dermatitis herpetiformis, which began with the siege of Toulon and lasted for nine or ten years. The temporary "cure" effected by his physician coincided with the period of his life when he was able to rest and be relieved of the strain of his military campaigns. The author also thinks that Napoleon's characteristic pose with his hand beneath his shirt was a mannerism possibly cultivated in his boyhood. He does not think it was due to itching from his cutaneous disease.

This book is a most readable one and contains many references and interesting illustrations.

An Introduction to Medical Genetics. By J. A. Fraser Roberts, M.A., M.B., D.Sc., Principal Investigator to the Burden Mental Research Trust, Stoke Park Colony, Stapleton, Bristol. Cloth. Price, \$4.50. Pp. 266, with 94 illustrations. New York & London: Oxford University Press, 1940.

Works on human heredity have not heretofore been distinguished by any evident relevance for clinical medicine. In Dr. Roberts's volume, perhaps for the first time, the relation of genetics to medical practice, and especially to medical research, can be seen clearly. The author, moreover, by a somewhat novel method of presenting genetic principles has achieved a clarity and simplicity which are exceptional, in comparison not only with other textbooks but even with avowed popularizations of the subject.

There is no conventional prefatory section on genetic principles. Instead there is a discussion in turn of each type of mating which may be encountered in man: normal by abnormal, abnormal by abnormal and normal by normal, for conditions which exhibit respectively dominant, recessive or incompletely dominant inheritance, and autosomal or sex linked transmission. The discussion of each case is in terms of a familiar human abnormality and is followed by a clear explanation of the chromosomal basis for the observed results. Genetic principles, developed gradually in the course of the book, are limited strictly to those which are immediately applicable to human material. Special statistical methods, necessary for the actual analysis of human hereditary mechanisms but not essential for an understanding of them, are not elaborated, but the precautions which must be observed in the collection and interpretation of data in order to avoid the commoner statistical fallacies are carefully pointed out. Even so difficult a subject as the detection of human linkage is not ignored, and once again the author explodes the still current notion that the association of two abnormal traits indicates that they are linked in the genetic sense.

Topics of subsidiary importance or of especial technical complexity are relegated to fine type and may be omitted by the reader without sacrificing the continuity or coherence of the

remainder of the text. But in spite of the modest dimensions of the book it is doubtful whether any single principle essential for the understanding of human genetic methods fails to receive at least passing attention, with judicious orientation into what is already an unwieldy literature for the uninitiated.

There are inevitably some sections with which it would be tempting to take issue. Thus Roberts seems overoptimistic with regard to the prognostic possibilities promised by the prospect of constructing linkage maps for man. It is quite true, of course, that the accumulation of cases of genetic linkage is almost bound to follow any systematic effort to discover them. But it is a far cry from the discovery of isolated cases of linkage to the development of usable gene maps such as have been elaborated so brilliantly for *Drosophila* and maize. Even in the mouse, in which the difficulty inherent in a larger number of chromosomes is roughly of the same magnitude as in man, chromosome maps are still a dream for the future in spite of this animal's convenience for laboratory experiments and the extensive genetic investigations of which it has been the subject. This is not to deny the value of linkage studies in man but it does suggest the importance of pursuing human genetic studies as human genetics and of recognizing at the outset the conditions (not all unfavorable, as is frequently supposed) which establish the methodology of human heredity on a somewhat different level from that of the genetics of laboratory bred animals.

It is the special merit of the book that it reveals the conditions by which human genetics, especially in its medical aspects, is qualitatively distinguished from the conventional genetics of the animal or plant breeder. And it is important to recognize that the classic materials presented in standard biologic textbooks may give a misleading or totally false picture of what is to be expected in human material. The excellent sections on the similar effects of different genes, on the variable expression of heredity factors and on heredity as a factor in the causation of disease, together with constant emphasis on the peculiar significance of gene frequency in man, succeed in establishing the proper orientation. One gets the impression that the part played by heredity in a large majority of pathologic conditions is to determine the presence or absence of a constitutional peculiarity which might be called a diathesis, although it involves a more tangibly determinable condition than that term usually connotes. From the evidence available it seems almost certain that this situation is far commoner than is any unequivocal one to one correspondence between gene and disease. Genetic study can assist the clinician by making possible the detection of diathetic individuals even when they do not develop the disease, and this should facilitate the detection of such controllable nongenetic factors as infection, diet and mechanical irritation, which may play a part in transforming an inherited diathesis into a patent pathologic condition.

The reader should be warned that Dr. Roberts's theoretical discussions of the various ways in which genetic factors may be concerned in the development of disease have the appearance of being rather more speculative than need be. This is partly to be attributed to a commendably conservative approach but chiefly, perhaps, to the author's limiting himself exclusively to human heredity in his choice of illustrative material. In this connection primarily the disadvantages of this restriction are seen, for a judicious selection of well established analogues from animal genetics would have furnished a firmer basis for many of the inferences which appear rather tenuous when supported only by observations from the less adequately studied human material. For example, the author suggests that certain genes may act by rendering the developing embryo especially sensitive to environmental variations which are without effect on genetically normal organisms; the suggestion would appear less gratuitous if it were indicated that this type of action has frequently been demonstrated for genetic factors studied in laboratory animals. And the whole field of what is commonly called developmental or physiological genetics has such an intimate bearing on the specifically medical problems of human heredity that some familiarity with its methods and results would seem to be an indispensable part of the medical geneticist's background.

The defects which may be found in this volume are minor in comparison with the values inherent in its fresh outlook and in its temperate treatment of most problems. Of specific sections, the chapter on multifactor inheritance is perhaps the least satisfactory, and it would probably have been better to omit entirely a consideration of hereditary factors in intelligence if it was not possible to give somewhat more extensive indication of the complexities of the problem. The practical minded reader may be disturbed by the fact that many of the illustrations of clearcut mendelizing pathologic conditions are still such rare or insignificant aberrations as albinism, alkaptonuria or polydactyly. But an understanding of the book will involve recognition that this is largely a consequence of the inadequacy of traditional methods in human genetic research and an appreciation of the fact that the importance of genetics for medicine considerably transcends its relevance to such conditions as those just enumerated. The use of genetic methods as a tool to supplement the usual methods of clinical research is more than likely to shed light on the etiology and pathogenesis of leukemia, gastric ulcer and essential hypertension, for example, and to prove profitable in the further study of such infectious diseases as rheumatic fever and poliomyelitis, to name only a few of the conditions in which there is already some basis for inferring the importance of hereditary factors.

Medical practitioners and investigators will find the book a comprehensible and stimulating guide to the applicability of genetics to medicine. It can also be recommended to specialists in animal or plant genetics who wish a clearer idea of some of the human applications of their subject. And it should prove an admirable textbook either for a semester's course in the premedical curriculum or as the basis for a brief lecture series in genetics for medical students.

Expectant Motherhood. By Nicholson J. Eastman, M.D., Professor of Obstetrics in Johns Hopkins University, Baltimore. Cloth. Price, \$1.25. Pp. 176, with 9 illustrations. Boston: Little, Brown & Company, 1940.

This is another of the numerous books which have appeared during the last few years attempting to educate expectant mothers about pregnancy and labor. Not only has the author admirably succeeded in presenting this information in simple language, but throughout the book he allays possible fears and explains away absurd ideas and superstitions connected with childbirth. Every woman who reads this or a similar book will find out what occurs to her and her baby during pregnancy and labor. Furthermore, it will make her realize the great value of good antepartum care and the importance of selecting a good physician and a satisfactory hospital for her confinement. This book should be recommended to women who plan to have a baby.

Preventive Medicine. By Mark F. Boyd, M.D., M.S., C.P.H., Field Staff Member, International Health Division of the Rockefeller Foundation. Sixth edition. Cloth. Price, \$5. Pp. 588, with 168 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

The publication of the sixth edition of this standard textbook of preventive medicine is evidence both of the esteem in which it is held and the rapid progress of development in the field of public health. Its greatest usefulness is as a textbook in courses on preventive medicine in medical schools and universities and as a guide to physicians whose public health activities are largely incidental to clinical practice. The book has recognized standing.

The Early Diagnosis of the Acute Abdomen. By Zachary Cope, B.A., M.D., M.S., Surgeon to St. Mary's Hospital, Paddington. Eighth edition. Cloth. Price, \$3.75. Pp. 257, with 36 illustrations. New York & London: Oxford University Press, 1940.

This edition of Cope's famous monograph embodies few additions. Little can be said in further praise of this small but justly popular book that has not already been said in past reviews. A compact volume, it treats with utmost clarity the entire subject of acute conditions of the abdomen. Particularly excellent are the chapters on the method of examining the abdomen and the opening chapter on the principles of diagnosis. The importance of a detailed history is emphasized. Charts illustrating the reference of pain and manual methods of examination are distinctly helpful. Anatomic considerations are utilized to explain the basis for the various diagnostic procedures.

Well known to most, it should be pointed out that this volume has a place on the shelf of every student, surgeon and physician whose work may be even remotely related to pathologic conditions of the abdomen.

The Unseen Plague—Chronic Disease. By Ernst P. Boas, M.D., Chairman, Committee on Chronic Illness Welfare Council of New York City. Cloth. Price, \$2. Pp. 121, with 2 illustrations. New York: J. J. Augustin, Publisher, 1940.

As an administrator of a hospital a large part of which is devoted to the care of the chronically afflicted, as a clinician and as chairman of a permanent committee on chronic illness of the Welfare Council of New York City the author has had ample opportunity to study the various phases of the problem with which he deals. With the exception of mental diseases, tuberculosis and to a certain extent cancer, adequate provision has not been made anywhere for the care of the legions of sufferers from the diverse disabling and crippling illnesses. The book deals comprehensively and conscientiously with the medical, social and organizational aspects of the situation; it takes a discouraging view of the preventive possibilities which lie mainly in popular education and in clinical and laboratory studies on the causes and methods of treatment of the degenerative diseases. According to the author, only improved socio-economic conditions can bring about a real remedy. He develops this point of view in the chapter on public responsibility for the chronic sick, on page 47 of which he says rather impetuously:

An aroused community, in self preservation as well as for humanitarian reasons, must face the fact that the bare existence forced on so large a proportion of our population generates and accelerates disease and undermines the health of vast numbers of citizens. Steady employment, fair wages and proper housing will prevent more disease than most laboratory research and educational ballyhoo about disease prevention.

Neither such occasional outbursts as the one quoted nor the few minor statistical inaccuracies and some inconsistencies of statement detract from the value of the book and the serious challenge it presents to the medical profession and to every thinking man and woman. The best written chapter is that on the aged, and the one dealing with the community program for the care of the chronic sick is the most constructive. The book is provocative of thought and may stimulate not only interest in the problem but action to deal with it in a way its gravity demands.

Psychology and Psychotherapy. By William Brown, D.M., D.Sc., F.R.C.P., Hon. Consulting Psychologist, Bethlem Royal Hospital, Beckenham, Kent. Fourth edition. Cloth. Price, \$4.75. Pp. 260. Baltimore: William Wood & Company, 1940.

The publication of a fourth edition of this little book is ample evidence of its reception and appraisal. The contents frankly and unequivocally deal with psychiatry from a psychoanalytic point of view. Nevertheless, the contributions of all the great schools of psychology are considered and utilized when applicable. This is an excellent introductory book for students of psychiatry.

The Sexual Perversions and Abnormalities. By Clifford Allen, M.D., M.R.C.P., D.P.M., Physician in Charge of the Psychiatric Department of the Seamen's Hospital, Greenwich. Cloth. Price, \$2.25. Pp. 193. New York & London: Oxford University Press, 1940.

The author has with great courage attempted to consider the sexual perversions with a view to indicating the possibilities of therapy for them. His clinical material indicates a wide experience and his therapeutic results by a diversity of methods seem to have been gratifying. The possibilities of cure or amelioration of perversions without lengthy psychoanalysis are convincingly presented by the author from his own material.

La fotografía de las membranas profundas del ojo. Por Manuel de Rivas Cherif. Paper. Pp. 75, with 52 illustrations. Mexico: La Casa de España en México, 1940.

In this booklet there is a brief review of the history and optics of some of the more important cameras used in photographing the fundus of the eye. The pamphlet is well printed on good paper. The diagrams of the cameras and the optical aspects are not bad but the pictures of the fundi are so hopeless that they seem to have been developed under the influence of Rivera. The two color plates are worst of all, the fundus being depicted as a sickish pink-brown.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Reactivated Tuberculosis an Occupational Disease.—The employee in this case had pulmonary tuberculosis which had been in an inactive stage for some sixteen years. He was employed as a grain scooper, which work required him to go into the holds of grain ships and there to operate steam shovels by which the grain was brought within the reach of moving buckets. In the holds of such ships the air was impregnated with minute particles of husk, mustard-seed and dirt. Some time about the middle of the year of 1934 the employee began to have difficulty with his breathing, and his dormant tuberculous condition became reactivated. By June 15, 1936, he became totally disabled and filed a claim for compensation under the longshoremen's and harbor workers' compensation act. The commissioner awarded compensation, the United States district court for the western district of New York affirmed that award and the employer appealed to the United States circuit court of appeals, second circuit.

There was sufficient testimony, in the opinion of the court, to justify the conclusion that hard manual work done for long periods in dust-laden atmosphere tends to produce fibrosis of the lungs, which in turn weakens resistance to any latent tuberculous infection and reactivates that infection. This is what happened in the present case. The important question before the court was whether or not the disability was an injury arising out of employment. If so, it was either an "accidental injury" or an "occupational disease." The court agreed with the commissioner making the award in the first instance that it was an occupational disease. The court was of the opinion that the compensation act should not be extended so as to make it a general health insurance and that to avoid this the coverage must be limited to diseases resulting from working conditions peculiar to the calling. In order to recover a workman must, the court continued, be exposed to hazards greater than those involved in ordinary living, and the disease must arise from one of these hazards. But, although it must be found that special dangers exist in the employment and that the disease arises from such dangers, the court could see no reason for limiting the protected class to those who have a normal resistance to such diseases or for excluding those who are abnormally vulnerable. It might be desirable that the second group should not be employed under such conditions at all, but members of that group may not be charged with ignorance, carelessness or acceptance of the risk because they are. Such considerations, the court pointed out, are alien to the underlying theory of workmen's compensation, which makes industrial disabilities, so far as they are truly attributable to the industry, a part of the cost of production and throws compensation for them on the consumer. This is not because the consumer is at fault for creating the demand whose supply produces the disabilities but because a loss shared among many is less a loss than if borne by one. Since all who actually work in the industry are necessary to the supply, the injuries of all, whether or not they are normally resistant to the unwholesome conditions pervading it, are part of the cost of producing that supply, and compensation for them is within the scheme. It would be an especially harsh interpretation which would exclude just those who are most in need of protection.

The court could see no difference between an acute infection and the awakening of an old one. The compensation act is not concerned with pathologic conditions but with industrial disability; a disease is no disease until it manifests itself. Few adults, the court said, are not diseased, if by that is meant only that the seeds of future troubles are not already planted, and it is commonplace that health is a constant warfare between the body and its enemies. An infection mas-

tered, though latent, is no longer a disease, industrially speaking, until the person's resistance is again so far lowered that he succumbs. It was contended that so broad a construction of the compensation act would result in premiums going to prohibitive heights or that all persons who enter a calling must be examined and the weaker ones excluded. It is possible, the court answered, that the added cost of the system will so raise prices as to throw some workmen out of employment, but so far as it is true one must choose between cheaper and larger production, carried on with less regard for the producers, and a restricted output made under better conditions. Whatever the proper path, the court concluded, it was not for the courts to plot it, and it was enough that the award in the present case seemed to the court to carry out the scheme of the compensation act and fall fairly within the language chosen to embody it. The award in favor of the employee was therefore affirmed.—*Grain Handling Co., Inc., v. Sweeney, 102 F. (2d) 464.*

Malpractice: Death of 6 Year Old Boy Attributed to Chiropractic Adjustments.—Contending that the death of her 6 year old son was due to the carelessness and negligence of the defendant chiropractor, the plaintiff brought suit and obtained a judgment for \$10,000. The defendant then appealed to the district court of appeal of California.

The plaintiff, according to her testimony, first noticed that her son was "stooping a bit." He complained that it had been painful for him to stand erect since a boy bumped him at school. Later a weakness of the legs developed and the plaintiff and her husband took the child to the defendant chiropractor. After roentgenograms had been taken the defendant, according to the plaintiff's testimony, attributed the boy's condition to a misplacement of a vertebra. He then proceeded to give an "adjustment" and continued this form of treatment about every three days for nearly four months, until the boy died. After four or five adjustments the boy developed a temperature of about 100 F. During the course of treatment he lost vitality, weight and color, he complained of pain when the adjustments were being given, and "paralysis was coming from the legs to the arms, and he was completely paralyzed."

From time to time the plaintiff had conversations with the defendant with respect to the child's condition, and the defendant assured her that it was not necessary to call in a doctor because "the only thing the boy had was a certain pressure on the spinal cord, on account of the misplaced vertebra, and he was doing the best thing, and nothing more could be done for the child." The defendant was called as a witness by the plaintiff and he testified that he took roentgenograms of the boy's spine and found "a subluxation of the second cervical vertebra, impinging the nerves, and causing a congestion in the cord," as well as a "rotation of the second, third and fourth cervical." He admitted that he had made no laboratory tests, urinalysis, blood count or other test except the roentgen study and an examination of the spine with his hands, and he found no abnormality, swelling, tumor, contusion or abrasion other than the condition of the second cervical vertebra. He then testified, in part, as follows:

Q.—Did you make any diagnosis of his condition at that time? A.—In chiropractic, we don't use the term "diagnosis." I take it that you want to know if I placed a name on his condition?

Q.—Yes. I want to know if you came to a conclusion? A.—Yes, I came to a conclusion, but in chiropractic we term it "analysis" instead of "diagnosis." . . . My analysis was that he had a subluxation of the second cervical vertebra, causing an impingement of the nerves at that point.

Q.—Well, was that an impingement of the nerves or of the cord? A.—Well, it might have been from both. It was apparent from his condition that there was inflammation of the cord. The inflammation might have been from pressure on the spinal nerves, or upon the cord itself.

Q.—So, it was your finding and your conclusion that at all times, from the time of your first treatment to the last, there was some inflammation and congestion of the spinal cord at the region of the cervical vertebrae? A.—Yes.

A physician associated with the office of the county coroner testified that an autopsy which he performed on the body of the boy "showed the body thin, the lungs congested, the left lung being pneumonic, and both lungs studded with small

tubercles. The heart, liver and stomach were normal. . . . There was no evidence of spinal or other injury. . . . I had been informed that there was some spinal condition existing, and I therefore examined the spine to see if I could find any abnormality, which I did not find." He further testified that in his opinion the boy during the early stage of his illness had tuberculosis of the meninges of the brain, or coverings of the brain. "At that time," this witness testified, "he showed paralysis, which is a typical symptom of early meningitis." In reply to a question as to what effect a chiropractic adjustment of the second cervical vertebra would have when tuberculosis of the spine exists he replied: "It would be detrimental, as rest and quiet would be absolutely indicated in those cases" and that the adjustment would accelerate or increase the existing inflammation. Another doctor of medicine testified that the boy had "some form of meningitic irritation, probably tuberculous in character," and that he was probably suffering from a secondary tuberculosis of the spine. All these witnesses agreed that the chiropractic adjustments were contraindicated and that if the boy had received proper medical attention his chances of recovery would have been good. "I would say that the child died because of lack of proper medical attention, sanitary care and proper fixation," one of the witnesses testified.

In the opinion of the district court of appeal, there was substantial evidence in the record from which the jury could infer that the course of treatment persisted in by the defendant was not of that degree of care, diligence and skill possessed and used by prudent, skilful and careful practitioners of medicine practicing in the same vicinity. The court disagreed with the defendant's contention that the testimony of the doctors of medicine called by the plaintiff should have been excluded because they were not chiropractors. In so holding, the court quoted from *Hutter v. Hommel*, 213 Cal. 677, 3 P. (2d) 554:

We might add that we are cited to no rule obtaining in this jurisdiction and know of none which would preclude a physician trained in one medical school from testifying in a proper case as to the treatment rendered by a physician or surgeon trained in a different school. Such a rule might be promulgated where charges of negligence in a malpractice case are directed toward some special course of treatment to be tested by the general doctrine of a particular school, but it is not applicable to a case of this character where the alleged malpractice is based upon general charges of negligence relating largely to matters of almost common observation within the experience of every physician and surgeon.

The court could find no error in the record and therefore affirmed the judgment for the plaintiff.—*Abos v. Martyn* (Calif.), 88 P. (2d) 797.

Malpractice: Liability of Physician and Municipality to Patient in Municipal Institution.—A New York statute (Consol. Laws, ch. 24, section 50-d) imposes on a municipality ultimate liability for personal injuries sustained by reason of the malpractice of a physician or dentist while rendering services gratuitously to any person in a public institution maintained in whole or in part by the municipality. In the judgment of the Court of Appeals of New York, this statute creates a new remedy against the municipality in favor of the injured person. A physician or dentist who renders services to patients in such an institution and is negligent may still be sued on his common law liability for malpractice, but he has the right to insist that in accordance with the statute he be saved harmless by the municipality. The effect of any action, whether brought against the municipality or the physician or dentist, is determined by the provisions of the statute, and such action may be maintained only if the provisions of the statute relating to commencement of action and filing of notice of intention to commence action against the municipality are complied with strictly. Accordingly, the court held that the trial court had not erred in granting the motion of the defendants, a physician and others charged with malpractice incident to rendering services to a patient in a municipal institution, that the complaint be dismissed because the plaintiffs had failed to comply with the provisions of the statute pertaining to commencement of action and the giving of notice to the municipality of institution of suit. Judgment for the defendants was therefore affirmed.—*Derlicka et al. v. Leo et al.* (N. Y.), 22 N. E. (2d) 367.

THE AMERICAN RHEUMATISM ASSOCIATION

Seventh Annual Meeting, held in New York, June 10, 1940

DR. LORING T. SWAIM, Boston, Secretary

Mono-Articular and Pauciarticular Arthritis in Children

DR. WILLIAM T. GREEN, Boston: This report concerns a study of children with mono-articular arthritis involving the knee, and pauciarticular (paucitas, Latin, a small number) arthritis in which more than one and not exceeding four joints were involved. In all, forty-three instances of arthritis of the knee and thirty-five of pauciarticular arthritis were studied.

The results to date may be thus summarized: In the Boston area arthritis of mono-articular and pauciarticular type in children is more commonly nonspecific than due to syphilis or tuberculosis. In the pauciarticular and, to a lesser extent, in the mono-articular series, instances in which the symptoms and signs in the joints did not persist over two weeks were frequently found by later determinations to have been due to rheumatic fever. In both groups, when the symptoms and signs persisted over two weeks, they were likely to be prolonged with an average duration of 1½ years. In many of the cases of longer duration the relationship to atrophic arthritis was suggested because the joint manifestations in a large number of the patients were similar to those seen in generalized atrophic arthritis and because three patients in the pauciarticular and one in the mono-articular groups developed generalized atrophic arthritis after a quiescent period of several years. Lengthening of the involved extremity was a common feature in both groups. In twelve of the cases in which the knee was involved there was an average lengthening of 1.3 cm. with squaring of the epiphyses. The treatment, in mono-articular and pauciarticular arthritis of long duration, should be that used in atrophic arthritis. Traction is ideal to correct deformity and develop motion.

DISCUSSION

DR. J. ALBERT KEY, St. Louis: Long ago I heard Dr. Osgood say "When confronted with chronic progressive mono-articular arthritis in a child, the diagnosis is tuberculosis until proved otherwise." I still believe that statement. I do not know what toxic arthritis is. These cases impress me as infectious. Some of them may turn out to be rheumatic fever. Some of them may be true Still's disease. Surgery might be of value if one was assured that they would become chronic. Synovectomy might be definitely indicated. Synovectomy would prevent deformity; it might prevent recurrence, and it might cure the disease. What other treatment besides high vitamin diet does Dr. Green advocate and on what basis was a low carbohydrate diet given?

DR. WALTER BAUER, Boston: Arthritis confined to one or two joints in children is all too frequently called toxic arthritis, a vague, meaningless diagnostic label. Evidently the situation in children is not unlike that in adults, namely that a certain percentage of patients with a mono-articular or "pauciarticular" arthritis are suffering from an atypical form of rheumatic fever or rheumatoid arthritis. What the others represent can be told only by the passage of time and further follow-up studies. It is important to appreciate that joint involvement in rheumatoid arthritis is not always symmetrical, particularly at the onset. Thirty per cent of our patients were atypical in this respect. Until our knowledge of joint diseases is greatly enhanced, the use of the term toxic arthritis is equivalent to saying we do not know. Such being the case, is it not preferable that we label them diagnosis unknown and hope that continuous follow-up study will give us the correct answer in many instances?

DR. M. H. DAWSON, New York: Were antistreptolysin titers determined on these patients? Some of the cases in this group which eventually clear up without residual joint changes are possibly atypical manifestations of rheumatic fever.

DR. WILLIAM T. GREEN, Boston: The antistreptolysin titers have not been determined. I treat this type of arthritis of longer duration exactly as atrophic arthritis. The same problem is involved. In those of briefer duration, the same preliminary treatment should be adopted as that for rheumatic fever. The local treatment in the chronic group involves the active correction of the deformity. Traction applied to the joints allows correction of the deformity and active painless motion. Perhaps one of the reasons why joints do better under such a regimen is that motion stimulates absorption from the joints, as has been shown by Bauer and others. There is no definite justification for any dietary regimen in arthritis, yet in the majority of instances I have recommended a low carbohydrate and high vitamin diet. The general health of these children must be promoted in all possible ways. The best "medicine" is rest.

Heberden's Nodes: Heredity in Hypertrophic Arthritis of the Finger Joints

DR. ROBERT M. STECHER, Cleveland: The present study, confined to idiopathic nodes in white women, is an analysis of the families of sixty-four individuals with Heberden's nodes. All index cases were examined personally. Information about relatives was obtained by examination when possible, otherwise by correspondence or through the family history. Fathers and brothers are not included. Of sixty-two mothers of women with Heberden's nodes, twenty were said to be affected compared to 10.3 which would be found in the general population of a group of the same size and age distribution. In 117 sisters of affected people thirty were found to be affected, compared to 10.3 which would be the expectancy in the population in general. Among 109 sisters of unaffected people in a control series the condition occurred five times compared to an expectancy of 6.26. Various family combinations were noted. Of sixty-two families the mothers were involved twenty times. Three generations of women in direct descent were found in three families. Twelve families had more than one daughter affected. In only twenty-seven of the sixty-four families studied was no evidence of familial involvement discovered. In three families with multiple involvement the probability of such combinations occurring in the same family by chance alone were found to be 1 in 190, 1 in 4,500,000 and 1 in 10,000,000 families. As Heberden's nodes is essentially a disease of later life, it seems unlikely that a common environmental factor was responsible for the condition in several members of the same family. The condition found among families of patients with Heberden's nodes is best explained by a strong hereditary influence.

DISCUSSION

DR. MORTON D. SCHWEITZER, New York: There is a substantially higher incidence among the sisters and mothers of the index cases than in the control series. I should reckon the probabilities in the three pedigrees differently. The total probability in a family is the sum of the probabilities of each member. By this method the results would also appear significant, although smaller than Dr. Stecher finds. I regard this as suggestive of a possible hereditary basis, but not proved, since the other factors suggested by Dr. Stecher as possibly operating in this condition

might also occur more frequently in the family group. There are several technics appropriate for this type of study. A "gene frequency" analysis is particularly useful in the study of conditions which occur as frequently in the population as do Heberden's nodes. Since it is difficult to get all members of the family into the clinic for study, mother-daughter correlations might prove of value. Dr. Stecher, is there any possible relationship between traumatic and idiopathic nodes to be considered and may there be common susceptibility factors underlying the two types? With regard to the sex, the principal difference in the tables is a delayed onset in males of about ten years, in comparison with females.

DR. HOMER F. SWIFT, New York: Has Dr. Stecher analyzed the susceptibility of these patients to trauma? Are their hands specially exposed to injury? From the hereditary standpoint were the siblings compared with the patients in reference to exposure to functional trauma? This factor would be different in a man working in an office and using a pencil and in a scrub woman or a stone mason. In several cases recently observed one or two finger joints specially subjected to functional trauma developed arthritis while the less vigorously used joints remained normal.

DR. J. ALBERT KEY, St. Louis: There is a strong hereditary factor in hypertrophic arthritis. Trauma may produce it experimentally, but clinically there are a great many cases in which it is not produced by trauma. Heberden's nodes are seen in old ladies who have done no manual work in their lives.

DR. RUSSELL L. CECIL, New York: Both my father and my mother developed Heberden's nodes in the fifties. I have no Heberden's nodes. I have tried to explain this in various ways. My father was raised on a farm and, as a young man, used his hands a great deal; then he became a clergyman and used his hands but little. My mother was energetic, always sewing or darning, and used her hands a great deal. The only hard use I ever put my hands to is playing golf. My feeling is that the reason I have not developed Heberden's nodes is that I have not used my hands. I think the condition is largely the result of trauma.

DR. CURRIER MCEWEN, New York: It has been said that if trauma does play a role we should see Heberden's nodes especially in stenographers who reach the age at which osteoarthritis is common. I have not been struck by any undue occurrence of Heberden's nodes in people who used their hands in laborious work in their earlier days. This raises in my mind the question just what part trauma plays in Heberden's nodes. Three of my patients have Heberden's nodes on one hand and not on the other. In the hand in which they do not occur there had been peripheral nerve injuries with quite obvious trophic changes in the skin. In one of these patients three fingers are useful and two are paralyzed on the injured hand. There are marked Heberden's nodes on the good hand and moderate ones on the usable fingers of the injured hand, but no sign of them on the paralyzed fingers. I wonder if that speaks for the traumatic theory, since these fingers cannot be used and hence are spared trauma, or whether some trophic change prevents the formation of the nodes on those fingers.

DR. HOMER F. SWIFT, New York: In studying the influence of trauma on the causation of disease one is liable to emphasize that inflicted by external or physical forces and to neglect that arising from internal or functional factors. Drs. Smadel, Farr and I have studied this question in the induction of chronic nephritis in rats and have found that hereditary and functional traumatic factors are both important and cooperative. Acute nephrotoxic nephritis was induced in rats; when the work the kidneys performed was reduced to a low level the nephritis disappeared. When, on the other hand, the diet contained sufficient protein to maintain a normal rat in health, i. e. 18 per cent nitrogen, and the kidneys were forced to excrete that amount, one strain of rats developed severe chronic progressive nephritis. In two other strains this tendency was less marked, and chronic kidney disease was best induced by an abnormally high protein diet. In stating my original question, therefore, I did not wish to neglect the influence of heredity in the induction of arthritis but to emphasize the contributory influence of functional trauma. A full analysis of etiology would doubtless embrace both factors

as well as others, and only by keeping alert to all possibilities will one determine the ultimate answer.

DR. DAVID H. KLING, Los Angeles: Would Dr. Stecher clarify the definition of Heberden's nodes? Does he classify spur formations visualized by x-ray examination as Heberden's nodes as well as new bone formation seen in hypertrophic arthritis or does he designate any kind of swelling of the phalanges as Heberden's nodes? I have seen periarticular cystic lesions containing a gelatinous fluid that persist for years with no evidence of bony spur formation. Perhaps in these cases trauma may provoke cystic lesions, owing to degeneration of the soft periarticular tissues.

DR. PHILIP S. HENCH, Rochester, Minn.: One of my patients, an elderly woman, had had infantile paralysis as a child with resultant partial paralysis of one arm and hand. Despite persistent atrophy and arrested development of this hand she had slowly regained considerable use of it, probably 50 per cent normal. Years later definite Heberden's nodes developed on the fingers of her normal hand but not a sign of them appeared on the partially paralyzed extremity. Does this not suggest that some trophic factor, rather than mere age or trauma, plays a role in the production of Heberden's nodes?

DR. RALPH PEMBERTON, Philadelphia: There are many factors in the situation which have not been analyzed as yet and are possibly not susceptible to analysis. Thus when one considers familial incidence one must also consider topographic and geographic factors as well as traumatic and nutritional influences. However, there are probably few who can escape the conviction of at least occasional familial trends operative in both major aspects of the problem. In a series of 500 cases which my associate Dr. Bach and I have been studying, the evidence of hereditary influences is almost the same in the two major groups, namely atrophic 50 per cent, hypertrophic 42 per cent, mixed type 44 per cent. The relationship which Heberden's nodes bear to the syndrome of hypertrophic arthritis as a whole is perhaps not wholly clear. Dr. Stecher's remarks, however, coincide with the views of those who find it difficult to believe that hypertrophic arthritis is a manifestation of age and trauma alone.

DR. ROBERT M. STECHER, Cleveland: I hope that the more technical methods of genetics which Dr. Schweitzer has discussed can be applied to these data with profit. Tentatively Heberden's nodes seem, at the present time, to be inherited as a single chromosome factor which is sex influenced, being dominant in females and recessive in males. This lacks substantiation. Dr. Pemberton has mentioned other possible factors of etiology. Common environment is pretty well ruled out because Heberden's nodes occur in middle and late life long after sisters have ceased to live together. A common environment does not account for occurrence in three generations. Climate was not considered in the study on incidence. This study was confined to Cleveland, to people of the working class who attended public clinics. In the family studies, sisters were widely separated geographically. Social and economic differences were not considered in the incidence studies. However, I feel certain that inclusion of members of the leisure or wealthy class to the proportion in which they occur in the population in general would not materially affect the incidence statistics. My conclusions concerning trauma may seem rather dogmatic but they are based on extended inquiry from many affected persons. Traumatic arthritis of one finger or of several fingers on the same hand occurs after definite injury, a single episode of such severity that it is definitely recalled. I do not believe that it is proper to confuse trauma with ordinary use and function. Playing a piano or using a typewriter should not be considered trauma. Dr. Kling asks whether heredity plays a role in hypertrophic arthritis. The most that has been found in the literature is that hypertrophic arthritis runs in families or that 20 per cent of the families show more than one involved member. Such statements mean little because no information is available as to the proportion of involved to noninvolved persons in these families. Dr. Cecil has not told us how many siblings were born or lived to an age when Heberden's nodes might be expected in his family. If my theory is correct and the condition is recessive in males, we would expect only one half the men to be affected if the mother was heterozygous, all the men affected if the mother

was also homozygous. If the father has Heberden's nodes, one would expect all his daughters to be affected regardless of the condition of the mother. I have seen one case similar to that described by Dr. Hench as well as another with peripheral nerve injury. The first of my patients had a daughter with Heberden's nodes, the second had a sister with Heberden's nodes. Three cases have been described in the literature of Heberden's nodes appearing after the patient suffered a hemiplegia. In these instances the healthy side alone was affected. Two patients had hemiplegias after Heberden's nodes had developed. After about a year's duration, no observable change has been noted in the nodes on the paralyzed side. I do not believe that trauma plays any part in such cases.

Local and Regional Analgesic Injections in the Treatment of Intractable, Nonsurgical Shoulder Conditions

DR. OTTO STEINBROCKER, New York: Analgesic solutions have been used for the past four or five years for diagnosis and treatment in arthritis and related musculoskeletal disease in the clinic in which I work. This report embraces our therapeutic experience with analgesic injections for the disabled shoulder. Before such treatment is undertaken complete examination, in doubtful instances necessary studies to rule out visceral pain, at least a tentative diagnosis, and a course of the usual medical and physical therapy are carried out as a matter of routine. Only a small percentage of affected shoulders were so refractory to other, accepted measures as to require analgesic injection. This treatment may be accomplished by (1) local, deep deposit of medication at the site of maximum tenderness, (2) regional supraclavicular brachial plexus block, (3) cervicodorsal paravertebral nerve block or (4) sympathetic (stellate ganglion) injection. The sympathetic approach is required occasionally for postherpetic and postamputation neuralgias. In the last few years we have had to resort to the paravertebral cervical block in only three cases.

Local injection at the site of maximum tenderness was employed for circumscribed fibrositis (fibromyositis, myofascitis, myositis) about the shoulder and neck, peripheral neuralgia and subdeltoid bursitis. In the majority of cases such treatment produced lasting effective results when the symptoms were due to referred pain. Local lesions were accompanied in some instances by secondary pain and tenderness in a surrounding halo or referred down the extremity. The secondary symptoms also responded when the peripheral source of trouble was correctly located and infiltrated. These circumscribed, peripheral disturbances often were eliminated by from one to ten injections of 2 to 15 cc. of 1 per cent procaine hydrochloride or equivalent aqueous solutions at intervals of from one to twenty-one days. In stubborn cases from 1 to 5 cc. of 2 per cent procaine base in oil was used. When repeated local injection failed, reconsideration of the diagnosis became necessary and brachial plexus block was utilized, when indicated.

We have found the supraclavicular brachial plexus block, with the Labat technic, a practical and effective procedure applied in our clinic without complication to ambulatory patients presenting intractable pain and disability of the shoulder region. The disorders treated by this method were diagnosed in the order of frequency as fibrositis of the periarticular and neck regions, osteo-arthritis of the cervicodorsal spine with referred symptoms, subdeltoid bursitis, rheumatoid arthritis (inactive), cervicobrachial neuralgia (due to pressure from fibrositis about the plexus or scalenus anterior involvement?) and osteo-arthritis of the shoulder joint (coraco-acromial, scapulohumeral). The conditions included in this group show a more or less identical symptom pattern dominated chiefly by pain referred down the extremity with limited abduction and rotation.

The severity of these symptoms in each case reflects the progress of the vicious cycle common in musculoskeletal disorder—pain, muscle spasm, postural deficiency, disability, deformity and trophic disturbances. According to our experience the cycle may be alleviated or abolished in selected cases by the use of the brachial plexus block with procaine solution. This technic was employed by us whenever possible in conjunction with manipulation, exercise and physical and medical measures which frequently had proved ineffective before blocking. Of seventy-six patients with intractable, usually chronic, shoulder

disorders, 73 per cent were greatly to completely relieved of symptoms and disability after from one to fourteen injections, averaging six, of 20 to 40 cc. of 1 per cent procaine solution or equivalent medication given at intervals of two to seven days.

DISCUSSION

DR. EZRA LIPKIN, Detroit: Following the publication of Dr. Steinbrocker's article in the *Annals of Internal Medicine* of June 1939 I injected 100 patients suffering from so-called rheumatic conditions with aqueous and oily solutions of procaine hydrochloride. Among these were forty-five patients with periarthritis of the shoulder, with negative x-ray appearances, who were treated by means of brachial block. The chief complaints were pain in the shoulder and arm, and limitation in abduction and external rotation. Following a number of regional injections of 1 to 2 per cent aqueous procaine hydrochloride solution—the average being three—there resulted either complete recovery or marked improvement in thirty-three of the forty-five patients, or 73 per cent—a figure which coincides exactly with that obtained by Dr. Steinbrocker. The period of observation extended up to eleven months. The anesthesia in the arm following the injection of the brachial plexus lasted from two to three hours and gave way to analgesia lasting from four to seven days or longer in some cases. Subsequent injections diminished the pain still further until there was complete remission or marked improvement of the symptoms. The one remarkable feature observed in the brachial block injections was the almost immediate relaxation of muscle spasm. I did not follow the injections with passive manipulation. Rather, the patient was encouraged to engage the arm in active exercise, which, because of freedom from pain, he was now able to perform. There were no untoward effects except for transient dizziness and numbness in the arm. When the brachial plexus is touched, the patient experiences a sudden, electric-like sensation in the arm. The solution is injected at this point. I used from 10 to 12 cc. of aqueous solution of procaine, although amounts up to 30 cc. have been recommended. Better results can be expected when the solution is injected directly into the nerve plexus rather than around it. Originally I employed the technic of Labat, injecting the solution in three areas, radiating from the single intradermal wheal 1 cm. above the midclavicle. To minimize trauma I reduced the number of points injected to one, namely, that aimed at the first rib. The results appeared to be as satisfactory as when the three injections were used, provided the brachial plexus is infiltrated, rather than the tissues around it.

DR. E. A. ROVENSTINE, New York: Nerve block or local infiltration procedures with analgesic solutions in painful non-surgical conditions as a therapeutic or diagnostic measure is rapidly gaining a wide and more important usefulness. Local anesthetization is no cure-all for somatic pain. The procedure should never be substituted for an extensive attempt to discover the cause of pain and never be performed, unless as a diagnostic measure, until such an attempt has been made. As a more accurate neuro-anatomic approach to the problem of shoulder pain my associates and I block the suprascapular nerve at the lesser scapular notch. Our desire for blocking the nerve is based on the knowledge that its sensory components form a vital pathway for pain fibers from the scapulohumeral and acromioclavicular joints and periarticular structures about the shoulder joint. The articular and periarticular branches leave the nerve in the supraspinatus and infraspinatus fossae, so that to obtain interruption of all the sensory impulses transmitted over the nerve it is ideally blocked at the suprascapular notch. The details of the technic have been worked out in the anesthesia department at Bellevue and the favorable results seen have encouraged its continued use.

DR. J. ALBERT KEY, St. Louis: In my experience people who have analgesic injections for subdeltoid bursitis go home, the anesthesia wears off and then some of them may have terrible pain. With the use of nupercaine and oil it has been shown recently that the patient may get a prolonged anesthesia which goes on to actual degeneration of the nerve and permanent paralysis. My experience has been with the use of procaine in acutely inflamed bursae. Those can be cured. With the chronic conditions I have had relatively little luck, not anything like the percentage shown here.

DR. WILLIAM T. GREEN, Boston: More emphasis should be placed on diagnosis in making decisions as to the type of therapy to employ. In certain cases of back pain we have injected a solution of procaine into the skin over the area which was sensitive to palpation, followed by the disappearance of all tenderness. Most often the relief was temporary, but I have been amazed to see certain patients remarkably improved—though I do not recommend this as fundamental therapy. I do use local irrigations in the therapy of bursitis and tendinitis, as seen most frequently about the shoulder. After preliminary local anesthesia, two needles of 18 or 19 gage caliber are introduced into the calcific area, and through and through irrigation is carried out with physiologic solution of sodium chloride. It is my feeling that the excellent results obtained are due not to the injection of procaine hydrochloride on any analgesic basis but rather to the mechanical factors which are involved. Often calcific material may be obtained from such irrigation and in those cases in which we are unable to obtain it we lay particular stress in multiple needling of the involved area. The results in this procedure are satisfactory, particularly in the acute cases. In general, I am against analgesic injections, particularly of the type represented by a brachial plexus block, unless the process cannot be treated locally or the pain is intractable. It is my experience that passive motion is inferior to active motion or active guided motion in almost all instances.

DR. JOHN P. STUMP, New York: Dr. Steinbrocker has used the term "nonsurgical" in his title. That word means that his patients have been through the hands of internists, orthopedists and neurologists without relief before he has employed his method of nerve block. His results have been gratifying.

DR. A. S. GORDON, Brooklyn: What relation, frequency and association does Dr. Steinbrocker find between painful shoulders and local tender points along the cervical spine of the same side? What experience and success did he have in injecting other joints, particularly the knee joint?

DR. OTTO STEINBROCKER, New York: I consider it wise to avoid injecting directly into a nerve. Occasionally in the course of a routine block a nerve may be traumatized when the needle penetrates it and some later discomfort arises. It is advisable in ordinary therapeutic procedures to employ perineural injections. Of course following any type of block temporary local discomfort may occasionally appear shortly afterward or when anesthesia wears off. When it occurs, this reaction is transient and is thought to be due chiefly to the hyperemia produced. As far as my observation goes, I agree with Dr. Key on the treatment of acute bursitis. The methods I have described were applied to chronic bursitis. Proper diagnosis is a complex problem in many of these cases before blocking is done. It is at times difficult enough to decide on the wisdom and method of injection even after thorough diagnostic study. In some borderline situations, proper block may prove of diagnostic as well as therapeutic value. I try to determine the importance of mechanical factors before I begin treatment. Merely to inject a patient with obvious skeletal defects causing symptoms, or while he is receiving corrective therapy for poor body mechanics, is of course not advisable. Exceptions to this rule are individuals with persistent localized areas of pain and muscle spasm which delay improvement. Injecting such foci of irritation has been found a helpful adjunct, hastening response to other measures. Coronary and other cardiac disturbance complicated or obscured by parietal spine or shoulder symptoms may present difficult problems of diagnosis and treatment. If the complaints are not of cardiac origin, I use whichever procedure is indicated for the musculoskeletal condition. Unless moribund, the average cardiac patient takes block well and the resulting relief of discomfort helps in every way. If the pain is thought to be definitely cardiac in origin, particularly coronary, sympathetic (stellate) injection is indicated. If the origin of the symptoms remains doubtful and relief is imperative, local procedures are first used, then brachial plexus block and finally sympathetic injection. The problem of differential block in these conditions is not conclusive at this time. There are many phases of the subject of analgesic injections requiring further investigation and improvement but, correctly applied, those procedures now available are helpful in the relief and control of pain and disability in many conditions.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Hemolytic Disease in Infants.—Abt reports three cases of hemolytic anemia in early infancy. The symptoms in one were observed at birth and in the other two at 4 months of age. A familial history could not be obtained. In early infancy the anemia is often a more pronounced symptom than icterus and is generally severe. The onset of the disorder may be insidious or it may occur as a severe hemolytic crisis and terminate fatally. Splenomegaly is usually of a considerable degree. When symptoms appear early, the first crisis is apt to be most severe. A severe crisis occurred in one of the cases. In the other two there were frequent crises which, though not so severe, necessitated transfusions at intervals of from three weeks to three months. Jaundice may be entirely absent even though there is indisputable evidence of blood destruction. The increase in reticulocytes is considerable. Increased fragility of the erythrocytes has been one of the usual criteria for the diagnosis of the condition. The leukocytes are generally normal or somewhat increased, and the platelets are usually within normal limits. An increase in normoblasts is generally observed. Bilirubinemia is always present. The icteric index is increased, and the indirect van den Bergh reaction is positive. Smears of the bone marrow obtained by sternal puncture reveal an increase in nucleated erythrocytes, a characteristic of hemolytic disease. General glandular enlargement is not usually observed in early infancy and was not present in the author's patients. There were no skeletal changes. Ocular lesions have not been reported in infancy. The crises of the disease show varying degrees of severity and different manifestations. Generally, infants manifest prodromal symptoms (lassitude, lack of appetite and fretfulness) followed by deepened jaundice and increased anemia. Usually during the periods of crisis the spleen enlarges and the urine becomes dark. Abdominal symptoms have not been characteristic of the condition in infancy. Occasionally crises are initiated by febrile attacks, when the symptoms are magnified and the infant may be extremely prostrate. Periodicity in the occurrence of crises is the rule. In one of the infants crisis occurred every three weeks, in another approximately every three months and in the third a single severe crisis occurred. The extent of jaundice and anemia vary considerably from attack to attack. The amount of urobilin in the urine is increased, especially after a crisis. Occasionally hemoglobinuria may be observed. The stools are normal but occasionally dark. Acholia is never present. Blood

transfusion and serum are temporary therapeutic aids which effectively combat an acute crisis. Splenectomy is the permanent therapeutic measure, and its expectant benefits outweigh the operative hazards. Accessory splenic tissue should be searched for and removed at the time of operation. Two of the author's patients have successfully undergone splenectomy at the ages of 15 months and 2½ years, respectively. In the third there has been no recurrent crisis during the ten months following the initial attack, and no splenectomy has been performed.

Hepatic Function in Icterus Gravis.—Zuelzer and Bigler cite two cases to emphasize the importance of hepatic damage in certain cases of icterus gravis neonatorum. The two cases occurred in one family; one illustrates a protracted course resulting in cirrhosis and the other an acute phase of hepatic damage. Both cases were associated with an unusual derangement of carbohydrate metabolism on the basis of hepatic dysfunction which is rarely observed in infants. Both patients died, one after a survival of eight months which finally ended in cirrhosis and the other at the end of the first week of life with kernicterus. Severe fatty changes, hemosiderosis and deposits of bile pigment were found in the liver. No clinical or pathologic evidence of erythroblastosis was present in either case. The metabolic disturbances (insulin-refractory glycosuria, hyperglycemia, absence of ketosis and sensitivity to insulin) are interpreted by the authors on the basis of the pathologic observations as a manifestation of impaired hepatic glycogenesis. After insulin therapy, insulin-like reactions without associated hypoglycemia and anatomic damage to the brain were observed in one of the cases. The possibility of a direct toxic effect of insulin on the central nervous system in the absence of hypoglycemia is considered and a tentative explanation is submitted.

Homotransplantation of Preserved Cornea.—Fine attempted to determine the relative merits of immediate and delayed transplantation of the cornea by controlled experiments on rabbits. Thirty-one animals were given partial penetrating transplants into normal corneas from eyes that had been enucleated at death and preserved for from twenty-four to fifty-two hours at a temperature of 4 C., as described by Filatov. The results obtained were compared with those of a control series of twenty-five rabbits in which homotransplants were performed with corneal tissue removed within twenty minutes after death. In the control group 52 per cent, or thirteen, of the operations resulted in grafts which were transparent to such a degree that the fundus could be seen through the graft. If one third of the transplant showed this degree of transparency, it was considered successful. In four of the thirteen clear grafts there were single narrow anterior synechiae. These did not result in vascularization or opacification of the transplants even after six months. In the thirty-one delayed transplantations (from twenty-four to fifty-two hours) there were ten clear grafts (32 per cent). Of sixteen operations with corneas preserved for twenty-four hours, seven resulted in transparent grafts and of fifteen operations with corneas preserved for forty-eight or more hours only three resulted in satisfactory grafts. The primary causes of opacification in corneal transplants are poor nutrition of the graft, infection, incarceration of the iris in the operative wound and vascularization. Secondary to these causes are poor adaptation of the margins of the graft to the host's cornea, marked early edema of the graft, corneal fistula, pressure from sutures on the surface of the graft, suture infection and folding of Descemet's membrane. When vascularization

Vitamin D Preparations for Psoriasis.—Thacker used viosterol, crystalline vitamin D, a mixture of western fish oils, a special concentrated cod liver oil in capsules and a stock concentrated cod liver oil internally for the treatment of twelve persons afflicted with psoriasis. Concentrated cod liver oil in a vanishing cream base was applied to the psoriatic areas. The lesions of nine patients disappeared following treatment with the stock concentrated cod liver oil and the special concentrated cod liver oil in capsules. Two patients failed to respond to this therapy and the condition of one was slightly improved. The daily amount of vitamin D in the stock concentrated preparation used varied from 500 to 945 units per kilogram for the fifty-two to the ninety days during which it was given. The special concentrated cod liver oil in capsules required approximately twice this amount before the psoriasis disappeared. The first five persons treated have been free from psoriasis since treatment was terminated about one year ago. Psoriatic lesions failed to regress after the administration of seven or eight times as much vitamin D in the form of viosterol and crystalline vitamin D as that of the concentrated cod liver oil. The areas of psoriasis

occurred in fresh tissue grafts it resulted from the adherence of the iris to the posterior surface of the corneal wound or actual incarceration of the iris. In contrast, with preserved grafts vascularization for the most part was superficial and proceeded from the limbal loops as a result of degeneration of the superficial layers of the graft. Eight iris adhesions were encountered in the control group and five in the series of delayed transplants. The author concludes that until more conclusive evidence of the superiority of preserved cornea for keratoplasty is forthcoming the conservative surgeon will choose fresh tissue, if available, or tissue preserved for a minimal length of time.

also failed to respond to the mixture of western fish oils. Therefore it appears that cod liver oil contains an unidentified antipsoriatic factor in a greater quantity than is present in the other preparations used. The sequence in the disappearance of the lesions is a profuse coarse scaling which occurs generally within three weeks after treatment is begun followed by thinning, fading of the redness of the base and a fine branlike scaling. After the lesions are gone the formerly involved areas are not to be distinguished from uninvolved areas. Local application of concentrated cod liver oil had no effect on the disorder. Psoriasis is probably due to a metabolic disturbance, the nature of which is yet to be determined.

Extrapleural Pneumothorax.—Since November 1937 Janes and his co-workers performed extrapleural pneumothorax on seventy-seven patients. Fifteen have since had oleothorax. The interval between the operation and the replacement of air with oil has gradually decreased. The shortest interval was three months. Despite the fact that a bronchopleural fistula developed in one patient soon after the injection of oil, the staff is becoming convinced that the injection of oil to maintain permanent collapse is desirable in many cases. Because of inadequate collapse one patient had a second operation. The extrapleural space was deliberately combined with a preexisting intrapleural pneumothorax in eight patients. Four of these have made satisfactory progress. Bronchopleural fistulas developed in three and a tuberculous and pyogenic empyema with spread of the disease into the opposite lung in one. The empyema finally cleared and the space is satisfactory, but a cavity persists in the opposite lung. These eight cases suggest that it is not advisable to connect extrapleural and intrapleural spaces unless the location and extent of the disease command it. Three patients have had

thoracoplasties since the extrapleural pneumonolysis. Eight of the seventy-seven patients have died; five deaths occurred within five or less weeks after operation and three were late postoperative deaths. The sputum was converted and the cavity closed in fifty of the sixty-nine living patients; the results were poor in the remaining nineteen, though three have subsequently improved following thoracoplasty. The authors conclude that unless with the further lapse of time the final result is not good the procedure should continue to be a useful collapse procedure.

Bacterial Endarteritis Complicating Patent Ductus Arteriosus.—Touroff and Vesell report four cases of subacute bacterial endarteritis complicating patent ductus arteriosus treated surgically. The rationale of the treatment is that ligation or excision often controls the bacteremia. For successful surgical eradication of the infection the vegetations should be confined to the ductus, and the ductus should be of sufficient length to permit excision. Unfortunately it is impossible to determine whether the vegetations are confined to the ductus, but certain information is available for the latter requirement. In the reported cases of operative uninfected patent ductus the length of the ductus varied from 0.5 to 1.2 cm. Practically all these operations were performed on children. It may be assumed that in adults the ductus would be larger. In three of the authors' cases the structure appeared to be of sufficient length to be divided and doubly ligated. If at operation the ductus is found too short the question arises whether operation is contraindicated. In the authors' first case the ductus was not completely excised but was divided and ligated as close to both orifices as possible. The interiors of the pulmonary artery and aorta were not inspected and the location of the vegetations was not known. The patient recovered from the infection following operation. This means that the vegetations were confined to the ductus and were completely excluded from the circulation by operation, or that they were also present in the pulmonary artery but healed quickly following closure of the arteriovenous shunt. If the latter were the case it appears that such spread would not contraindicate operation. If vegetations extend into the left side of the heart or the aorta, operation appears inadvisable as foci in these regions would continue to feed organisms into the peripheral circulation despite excision, division or ligation of the ductus. In the second case this was the sequence of events; therefore every effort should be made to determine involvement of the left side of the heart and aorta preoperatively. As subacute bacterial endarteritis superimposed on patent ductus is almost invariably fatal it appears justifiable to maintain that, barring the presence of major coexisting congenital cardiac anomalies or the generally poor condition of the patient, operation is contraindicated only in cases in which left-sided cardiac or aortic vegetations are present. The first of the authors' four adults recovered and has been well since operation nineteen weeks ago. The second patient was temporarily improved but the bacteremia persists seventeen weeks after operation. The third and fourth patients died of uncontrollable hemorrhage during operation. The recovery of one of the four patients affords little indication of the results regularly anticipated from such treatment, but since surgical therapy was successful in this case it should encourage others to give the method a thorough trial in the hope of reducing the mortality rate, which even the most optimistic observers place between 95 and 97 per cent.

Lobectomy and Pneumonectomy in Pulmonary Tuberculosis.—Dolley and Jones report seven cases of pulmonary tuberculosis, in four of which pneumonectomy and in three lobectomy was done. They advocate: (1) preliminary thoracoplasty with extrapleural apicolysis (while occasionally the final thoracoplastic stage may be included with the lobe or lung removal, they feel that this combined operation is usually inadvisable), (2) serial dissection of the hilar structures if technically possible, (3) the usual care in closure and burial of the bronchus, (4) immediate open drainage of the pleural cavity which by virtue of extensive thoracoplasty has become scarcely more than a broad slit, (5) painstaking removal by catheter suction of all possible infected material from the respiratory tract, (6) constant insistence during the early postoperative hours that the patient, with his pain controlled by analgesics, cough effectively and (7) minimal manipulation and instrumentation of the affected lobe or lobes preventing the purulent material within from

CURRENT MEDICAL LITERATURE

JOUR. A. M. A.

soiling the neighboring or contralateral pulmonary subdivisions. They believe that if, following thoracoplasty, it becomes apparent that a given patient is to remain disabled and his general condition warrants the surgical hazard and the technical difficulties are not too great, an attempt to remove the lobes involved is indicated. When bronchial stenosis is extreme or thick-walled cavities and extensive bronchiectasis exist which cannot be cared for adequately by extensive collapse or local compression this final measure is not justified until it is certain that nothing less radical will succeed. The final decision for lung removal is made after it has been found that extensive thoracoplasty is insufficient. Thoracoplasty is the preliminary procedure of choice. The authors are convinced that the removal of tuberculous lobes will become a reasonably safe and comparatively common procedure within the next few years. If the operative risks attain reasonable balance, lobectomy will be preferable to extensively necrotic lobe collapse. Contralateral spread is the most potential enemy at present. However, more and more potent weapons are being developed to combat it. Lobectomy should be limited at present to those patients for whom there is no other satisfactory recourse, and then only when the mediastinum and the chest wall have been stabilized and the residual potential empyema space has been minimized. Of their four patients undergoing pneumonectomy, two are dead and two will probably never regain their health. All had early or late contralateral spread. From the results in these patients the authors conclude that such patients should be prepared for pneumonectomy by thoracoplasty as more often than not the general condition of the patient is improved by thoracoplasty. Of the three patients on whom lobectomies of the right upper lobes were performed, two are well and able to work. The general condition of the third is excellent although her last sputum was positive. Toxic fatigue is notably absent in these patients, for their tuberculosis is gone with their lobes. In two, thoracoplasty preceded lobectomy; the postoperative course of all three was uncomplicated and in none was there a spread.

- Surgical Treatment of Gastric Cancer Masquerading as Benign.**—Walters and Cleveland believe that too often gastric and duodenal ulcers are grouped under the misleading title of "peptic ulcer" and their inherent dissimilarities neglected and thus not recognized as occurring in individual types of tissue in which pathologic reaction and response to medical and surgical treatment is different. A large chronic gastric ulcer (more than 2.5 cm. in diameter) in a patient more than 40 years of age, especially if perforation, obstruction or hemorrhage has been present, or one on the greater curvature or near the pylorus usually should be removed surgically without delay, as few of these lesions respond to medical treatment and many may be carcinomatous. The small gastric ulcer which has failed to heal or has recurred under adequate medical management should be

Cerebrospinal Fever.—Cushing states that from Nov. 11, 1939, to May 26, 1940, 124 patients with cerebrospinal fever differing from that seen in 1914 to 1918 were admitted to the Military Isolation Hospital, Aldershot, and treated with benzylsulfanilamide derivative by the intravenous route. The onset of the fever was sudden. Many patients went to bed feeling quite well and awoke in the morning with intense headache, frequently accompanied by vomiting. Incubation appeared to be from twenty-four to forty-eight hours. Some patients had various symptoms, especially sore throat or general malaise lasting one to seven days before the appearance of the headache. The fulminating septicemic type was even more sudden than this. Twenty-eight of the cases were classified as slight, 49 as moderate, 41 as severe and 6 as fulminating septicemic. The clinical picture was that of an extremely ill patient with the anxious expression of one in distressing pain. The lips and cheeks were pale and gray, showing a definite toxemia with much blood destruction. The skin was damp with perspiration. The most characteristic and distressing symptom was the intense and intolerable headache. The removal of from 30 to 50 cc. of cerebrospinal fluid would relieve the distressed condition immediately. The next important sign (in 116 cases) was nuchal rigidity with intense pain on attempting to approximate the chin to the chest. Vomiting was fairly constant and lasted from one to four days. During this stage benzylsulfanilamide derivative was valuable. Often the patient's mental condition was abnormal, presenting considerable cerebral irritation and mental depression. The temperature was no guide in establishing a prognosis or determining the severity of the case. Only 3 patients had a temperature of 103 F. on admission; 102 had less than 100 F. The pulse rate was much more indicative of the severity of the infection. A slow pulse rate was evident only in cases of increased pressure of the cerebrospinal fluid or in full dosage of the sulfonamide drug used. The reflexes followed no definite pattern. The patients with the fulminating type of fever showed meningeal signs; but the predominant clinical picture was acute generalized toxemia, and some were presumably septicemic in nature. In others the clinical picture simulated typhoid with pyrexia and a macular rash and in these cases the meningococcus could be isolated by blood culture. Within twenty-four or even twelve hours after the initial intravenous injection of benzylsulfanilamide derivative and lumbar puncture the temperature fell to normal, the intensity of the headache was diminished and in some cases entirely eliminated, nuchal rigidity lessened and vomiting ceased or lessened in persistence and severity. By this time sulfapyridine given orally in diminishing amounts caused no vomiting. Treatment was stopped in eight or nine days and the patient proceeded to uneventful recovery, was allowed up in from thirteen to twenty-one days and after four or five weeks of hospital treatment was discharged on five weeks' convalescent leave. After five weeks of convalescence 25 patients declared themselves perfectly well and fit, 48 complained of early fatigue on exercise and occasional dizziness, 6 complained of pain in the back and 42 exhibited effort syndrome in varying degrees of severity. Forty-eight were recommended for a period of light duty under the supervision of a regimental medical officer and 25 were returned to their unit as "fit for duty." For the others further convalescent treatment was recommended before their return to supervised light duty. The majority of the patients were young militiamen who contracted the infection after a short period of service. There were four deaths. Since May there have been eleven more admissions, and as no other deaths have

occurred the total mortality rate is brought down to 2.9 per cent. Benzylsulfanilamide, 20 cc. of a 5 or 10 cc. of a 10 per cent solution, is injected intravenously into one of the veins over the antecubital fossa. This can be repeated in four to eight hours, according to the severity of the case, and may be continued for three or four days until the patient's initial signs and symptoms disappear. The results were so constantly good and the effects so speedy that the drug is recommended for routine treatment at the outset in all cases except perhaps the mildest. Once the diagnosis is made, no further lumbar punctures are performed unless signs of intracranial pressure arise.

*Liver Function in Thyrotoxicosis. N. F. MacLagan and F. F. Rundle, with experimental data by H. B. Collard, F. H. Mills and F. F. Rundle.—p. 215.
*Action of Parasympathetic-Mimetic Drugs in Asthma. H. H. Moll.—p. 229.

Liver Function in Thyrotoxicosis.—MacLagan and his colleagues determined the hepatic function of forty-one patients with hyperthyroidism by means of a modified galactose tolerance test. Thirty of the patients showed definite impairment of hepatic function, and the remaining eleven gave results in the upper normal range (galactose index above 68). Clinical grading of the cases as severe, moderate and mild showed a definite relationship between the galactose index and the severity of the disorder. A significant correlation existed between the galactose index and the basal metabolic rate of untreated patients. Rest and iodine therapy had little effect on the galactose index, but in most instances thyroidectomy produced a prompt fall to normal values. Some residual impairment was demonstrated in a few cases studied at long intervals after thyroidectomy for severe hyperthyroidism. Daily subcutaneous administration of thyroxine to rabbits for periods up to seventeen days produced a marked impairment of tolerance to galactose injected intravenously. The livers of these animals also showed severe focal necrosis when examined microscopically. The galactose tolerance depends essentially on hepatic glycogenesis and this is the hepatic function which is particularly impaired in thyrotoxicosis and therefore the test reveals the typical disorder of the liver in this disease. It is possible that the toxic effect of the thyroid hormone on the liver is connected with its action in interfering with glycogenesis. The authors' data suggest that, when the galactose index is markedly high, structural hepatic damage is probably present. When the galactose index is only moderately raised their data do not show whether the change is a functional one or whether organic lesions are also present. The fact that normal limits were usually regained in fourteen days favors the functional explanation, and the fact that the iodine therapy has little or no effect suggests an organic cause. The galactose index provides an additional physical sign of hyperthyroidism.

Action of Parasympathetic-Mimetic Drugs in Asthma.—Moll observed the effect of mecholyl (acetyl-beta-methylcholine chloride) on twenty-eight persons with asthma and thirty-eight control subjects (normal medical students and non-asthmatic hospital patients with or without other types of respiratory disorders). He finds that the mecholyl test does not help to differentiate the different types of asthma, and patients with reflex asthma or persons in whom attacks are released psychogenically through nervous channels are not more susceptible to mecholyl than persons with infective or allergic asthma. However, the test may be helpful in the diagnosis between true asthma and respiratory neurosis, and especially hysterical hyperpnea: bronchospasm occurs in the former instance but not in the latter. The twenty-eight asthmatic subjects almost invariably responded with respiratory symptoms, which varied in intensity from slight wheeziness to severe asthma-like attacks. The control subjects showed general signs of parasympathetic stimulation (flushing, sweating, lacrimation and salivation) but chest symptoms did not develop. The tropism of choline derivatives for the bronchial system appears to be due not to a state of increased sensitivity of

the whole of the parasympathetic system (vagotonia) but only of the bronchial nerve endings or of the bronchial muscle itself. Pulmonary damage is an essential factor in determining the abnormal bronchial response. No matter how mild or infrequent the attacks of asthma may be, an asthmatic subject is nearly always susceptible to the drug. The asthma-like attack produced by choline derivatives is similar to, but probably not identical with, spontaneous asthma.

*Symptom of Narrowed Intervertebral Disk. H. Schaer.—p. 849.

*Primary Inoculation Tuberculosis of Vulva Caused by Cohabitation. M. Schmid.—p. 852.

Symptomatology and Therapy of Thyrogenic Migraine. E. I. Steuer.—p. 853.

Narrowed Intervertebral Disk.—Schaer directs attention to the fact that narrowing of the intervertebral disk is frequently encountered in diseases of the vertebral column. It is observed as an accompanying symptom of numerous degenerative changes of the intervertebral disk or of the adjoining vertebral bodies in the frequent spondylosis deformans. It is seen as a characteristic sign in juvenile kyphosis, in kyphosis of the aged and in osteoporosis of the aged. In all these cases the narrowing involves all or several of the disks. The narrowing of an isolated intervertebral disk occurs much less frequently and is difficult to diagnose. The author describes several cases in which this symptom was present and discusses the underlying pathologic process. Isolated narrowing of an intervertebral disk is due either to a reduction in its volume as the result of primary degeneration of the disk itself (osteochondrosis) or to pathologic processes in the surrounding tissues. The narrowing is found chiefly as an early roentgenologic symptom of tuberculous spondylitis. It is the result of the breaking through of the still intact intervertebral disk into a circumscribed diseased area of the adjoining vertebra. The deformation resulting from this breaking through leads to a seeming contraction, which at times is regular and at others irregular and which is frequently accompanied by a dorsal displacement of the vertebra above it. This early symptom of tuberculous spondylitis corresponds to the anatomic stage of the cavernous destruction of the vertebral body, a fact that has to be considered in estimating the age of a tuberculous process in the vertebral column.

Primary Inoculation Tuberculosis of Vulva.—Schmid maintains that in order to designate an extrapulmonary tuberculosis as a primary complex it is necessary to demonstrate the characteristics of the primary complex, namely a tuberculous inflammatory lesion at the portal of entry with swelling and caseation of the regional lymph nodes, and to rule out the existence of a tuberculous process in other parts of the body. The literature on primary extrapulmonary tuberculosis contains cases developing from ritual circumcision, from the injection of incompletely sterilized milk, from the piercing of ear lobes for the attachment of earrings, from injuries of the feet while walking barefoot, from contact with tuberculous cattle (in veterinaries and butchers) and from the kiss of patients with pulmonary tuberculosis. The possibility of a primary tuberculosis caused by cohabitation was demonstrated in guinea pigs in 1920. Five human cases of primary inoculation tuberculosis by cohabitation have been reported since 1929. The author reviews these cases and presents a detailed report of a case of his own. A woman aged 28 developed an ulcer at the attachment of the hymen a short time after defloration. Later the inguinal glands became sensitive to pressure. The diagnosis was undecided between syphilis, venereal lymphogranuloma and simple defloration ulcer. Repeated Wassermann and Frei tests were negative. Examination for gonorrhea was likewise negative. Some time later one of the inguinal glands perforated spontaneously, but the pus exuding from this gland contained no bacteria. Later several lymph nodes were excised and the microscopic examination disclosed caseous tuberculosis. Under a strengthening regimen, tuberculin therapy and local roentgen irradiation the lymph nodes decreased in size, the general condition improved and the vulval ulcer healed. Pirquet's tuberculin reaction was still strongly positive at the time of the

patient's dismissal from the hospital. The primary tuberculous complex on the vulva induced an examination of the cohabitation partner. This revealed tuberculosis of the prostate and of the seminal vesicles in a man who previously had been treated for tuberculosis of the bones.

*Sulfanilamide in Trachoma. J. Lijo Pavia.—p. 400.

Sulfanilamide in Trachoma.—Lijo Pavia, head of the Argentine committee for the prevention of blindness, reports on sulfanilamide treatment of trachoma of three groups of twenty-six patients each. These groups included children and adults. The disease was of the first, second and third degrees. The patients were not hospitalized; they remained at home in order not to be exposed to the sun's rays. The drug (azosulfamide) was administered on fifteen consecutive days in a daily dose of 0.02 Gm. for each kilogram of body weight for the first five days, 0.03 Gm. for the next five days and 0.04 Gm. for the last five days. The treatment was well tolerated. Photophobia, lacrimation, blepharospasm and conjunctival hyperemia showed improvement within the first five days of the treatment and generally disappeared in the course of it. Edema was reabsorbed, the pannus cleared and the transparency of the cornea and vision improved. The nodules became smaller and in some cases disappeared in the course of treatment or sometime after. Six patients were observed for three months after discontinuation of the treatment. Some of the patients instilled a drop of a 0.5 per cent zinc solution or an eyewash of a weak solution of mercuric oxycyanide. All the nodules had diminished in number and size and in some instances had disappeared. The author believes that sulfanilamide has an immediate therapeutic action on trachoma and a late action on the remaining nodules, with the probable exception of cases in which there are advanced forms of the disease. The patients had the treatment too recently to enable one to predict the future behavior of the disease and whether or not the results will be permanent.

Roentgen Diagnosis in Acute Abdominal Cases. G. Petré.—p. 1303.

*Hemorrhagic Disease in Newborn: Hypoprothrombinemia in Newborn. L. Salomonsen.—p. 1309.

Hypoprothrombinemia of Newborn.—Salomonsen states that all hemorrhagic conditions of the newborn are accompanied by a delayed coagulation time which depends on a hypoprothrombinemia due to vitamin K deficiency probably originating because of deficient formation of vitamin K in the sterile intestinal canal of the newborn. He asserts that giving a little cow's milk as early as from the second hour of life will almost wholly prevent this physiologic disturbance in coagulation.

Hospitalstidende

*Two Cases of Constitutional Infantile Anemia. P. Hjorth.—p. 1313.
Animal Experimentation on Heat Treatment of Malignant Tumors. K. Overgaard and H. Okkels.—p. 1317.

Constitutional Infantile Anemia.—Hjorth presents the cases of a brother and a sister, in both of whom, at the age of 8, a grave hyperchromatic anemia developed in the course of a few months with leukopenia and thrombopenia and hemorrhagic diathesis. There was hypoplasia, but not aplasia, of the bone marrow, also hypoplasia of the thymus and, in the boy, hypoplasia of the testes. Congenital bone deformities were present, clubfoot in the boy, bilateral luxation of the hip in the girl. The children were kept alive for two and a half years and four years respectively by means of blood transfusions, thirty in each case; no other treatment was of avail. A marked disposition to congenital bone deformities was established in the mother's family, and one member of the father's family was born without thumbs. These cases resemble five cases reported in the literature (Fanconi, Uehlinger and van Leewen) and designated by Uehlinger and van Leewen as "congenital infantile anemia."

THE UNIVERSALITY OF DIABETES

A SURVEY OF DIABETIC MORBIDITY IN ARIZONA

THE FRANK BILLINGS LECTURE

ELLIOTT P. JOSLIN, M.D.

BOSTON

WITH THE COOPERATION OF THE PHYSICIANS
IN ARIZONA

I believe that the incidence of diabetes should be highest in communities in which (1) the average age is greatest, (2) women predominate, (3) obesity is most frequent, (4) the proportion of Jews is greatest, (5) medical supervision is closest and (6) deaths are most accurately reported. Therefore I am puzzled to explain why the mortality from diabetes should be nearly twice as high in the United States as in Canada, when the two countries are separated only by an arbitrary line. Why should the incidence of diabetes double in the United States in the ten years 1880 to 1890 and then take thirty years to do so again—between 1900 and 1930? Why should it double in Italy and Switzerland between 1920 and 1934? Why should the death rate from diabetes in Rhode Island in 1937 be four times that in Arizona or, to make the question more general, why should the rate for Alabama, Arizona, Arkansas and New Mexico be the lowest in the country in 1937, 10 or less per hundred thousand, and that for Rhode Island, New York, Massachusetts and Connecticut be the highest, or more than 33 per hundred thousand?

Such thoughts were coursing through my mind when I received the flattering invitation of the executive committee of the Section on Practice of Medicine of the American Medical Association to deliver the Frank Billings Lecture.

An armchair statistical study of the incidence of diabetes does not appeal to me; field work does. Already there are available two excellent examples of the latter—the survey conducted in Massachusetts under the direction of Bigelow and Lombard¹ of the state board of health in 1929-1931 and that in Washington sponsored by the National Institute of Health² in 1935-1936.

These surveys, however, were concerned with the frequency of diabetes in areas in which its statistical mortality was reported to be highest. This left to me the opportunity to undertake field work in areas in which the incidence of diabetic mortality was reported to be the lowest. I reasoned that only good could come

from such a survey, because if the low incidence proved to be correct one could concentrate on a study of the cause for this immunity and might even encourage hereditarily predisposed diabetic patients to migrate to such a region. Contrariwise, if the survey showed that the information was ill founded, new cases of diabetes automatically would have been disclosed and brought under treatment, lives have been spared or prolonged and the diabetic army in the United States expanded. Moreover, of still greater consequence would be the outcome, if the evidence was frankly decisive and the reported low mortality completely overthrown, because it would put a question mark before every town, city, state or, indeed, country in the world which reported an extraordinarily low death rate from diabetes.

Where should such a survey be carried on? Obviously in one of those localities in which the reported mortality from the disease was the lowest, and in 1937 the four states were Alabama, Arkansas, Arizona and New Mexico. Alabama and Arkansas were at once ruled out by me because those states are too populous and they have too many doctors to make intimate contact possible. Arizona appeared preferable to New Mexico for the purpose because during the month of February it is said to be more available for investigation, and because Arizona is particularly diversified in climate, altitude and composition of its population.

Arizona having been chosen, the problem to be solved was why Arizona had a diabetic mortality of 10 per hundred thousand and Rhode Island one of 42 per hundred thousand in 1937, with three other states in the East—New York, Massachusetts and Connecticut—having diabetic mortalities more than 33 per hundred thousand. These mortalities were evidently not chance mortalities for a single year. This is shown in table 1, in which average mortalities are given for 1934 to 1938 of the states with the four highest and the four lowest rates. Here it will be seen that the higher rates range between 31 and 37 and the lower rates between 9 and 11 per hundred thousand of population, whereas the United States showed an average rate of 23.

While considering the possibility of making the survey, I sought advice and received it wholeheartedly from Dr. Herbert L. Lombard of the Massachusetts State Board of Health, who encouraged and, indeed, urged me to carry it on. I also received assistance in many ways from the Surgeon General of the Public Health Service, Dr. Thomas Parran, and from Dr. Louis I. Dublin and Mr. Herbert H. Marks of the statistical department of the Metropolitan Life Insurance Company and, finally, most valuable counsel from the editor of THE JOURNAL.

Certain contrasts between Arizona and Rhode Island first deserve mention because of their importance in explaining the wide differences in diabetic mortality. The area of Arizona is 113,810 square miles and more

than 100 times that of Rhode Island, which is 1,067 square miles. In Arizona much of the land is made up of reservations for the Indians, forests, parks and mountainous regions save those penetrated by main highways, and this makes communication difficult. In 1937 the estimated population of Arizona was 409,000 and that of Rhode Island 681,000. The density of population per square mile is 3.8 in Arizona and 644 in Rhode Island. The relative number of physicians to

TABLE 1.—States with Highest and Lowest Diabetes Mortality Rates per Hundred Thousand in 1937 and 1934-1938

	Highest			Lowest	
	1937	1934-1938		1937	1934-1938
Rhode Island.....	42.0	36.9	Alabama.....	10.6	11.0
New York.....	36.9	36.9	Arizona.....	10.0	9.8
Massachusetts.....	33.7	34.8	Arkansas.....	9.2	8.5
Connecticut.....	32.5	31.5	New Mexico.....	8.1	8.6
New Hampshire.....	32.9			

the population differs less than one might conceive, one to 772 in Arizona and one to 726 in Rhode Island, although in the urban areas in Arizona there are 27.6 physicians per 10,000 inhabitants and only 5.4 in the rural sections of the state. The population in Arizona in towns and villages less than 2,500 constitutes two thirds of the total inhabitants, but in the latter state it is hardly fair to class the population of many of the small towns as distinctly rural. The distance across Arizona from north to south is nearly 400 miles and from east to west 340 miles, as compared with 48 and 37 miles respectively for Rhode Island. How large a share possibilities for the medical supervision of the population count for the divergence in mortality of diabetes in the two states no one knows. Certainly it must be a factor, but in this discussion no percentage estimation of the part medical supervision plays will be adduced.

CRUDE VERSUS ADJUSTED MORTALITIES FOR AGE AND SEX

Diabetes is a disease in which the influence of the age and sex of the population is profound. These are well recognized facts. Table 2, compiled from data published by the National Health Board in its survey of 2,502,391 persons living largely in urban areas, enables one to see at a glance how misleading comparisons can be if based on crude statistical data alone. Thus only one diabetic individual can be found among 2,500 boys and girls and another among 1,700 young adults between the ages of 15 and 24 years. At these ages sex is indifferent, but above this level women predominate. At the age of 65 years one man in seventy has the disease and one woman in sixty. In Massachusetts over the age of 45 there is 1.1 female for every male. In Arizona the comparable figure is 0.73. Thus the simple adjustment by age and sex of the population in Arizona and Rhode Island resulted in the year 1937 from one to four to one to three, and, for the years 1929 to 1931 the crude ratio of one to three and five-tenths when adjusted to the census of 1930 falls to one to two. These standard compilations, therefore, made the task of explaining the difference in mortality less formidable, because with this aid half of the hurdles are passed.

CONTRIBUTORY CAUSES OF DEATH IN ARIZONA AND MASSACHUSETTS

The large number of deaths from tuberculosis in Arizona, 802 in 1939, compared with fifty-seven from diabetes furnished a chance opportunity to explain its statistically low diabetic mortality. Tuberculosis takes precedence over diabetes. If it could be demonstrated that as many patients with tuberculosis had diabetes in Arizona as in Massachusetts there would be a great accession in diabetic mortality data. In order to determine this, copies of Arizona death certificates bearing the diagnosis tuberculosis were made, and these were analyzed under the supervision of Dr. Lombard, but the results indicated only a fraction as many cases of diabetes among the tuberculous in Arizona and in fact all other groups in which diabetes occurred as a secondary cause, as in Massachusetts. For combined contributory causes the figure for Massachusetts was 11.3 per cent and for Arizona only 1.4 per cent. Such a striking difference suggests that in Arizona diabetes as a secondary cause of death frequently is omitted from the death certificate.

FIELD WORK

Statistical computations have changed the difference in ratio of diabetic mortality between Arizona and Rhode Island from one to four to one to two. To turn now to diabetic field work, the plan of campaign adopted was a direct outgrowth of a phrase, "the fecundity of the aggregation," once used and elaborated on in an informal evening discussion in his home, and later published, by Prof. Josiah Royce of Harvard.³ By it he meant that, when people get together and discuss things, something new and better is likely to arise than from one of the individual members of the group, uppermost in my mind was how I could secure this "fecundity of the aggregation" in Arizona. That was quickly solved, because first of all the Arizona Board of Health put its office, its staff, its publication and its good will at my disposal, and this action was quickly followed by that of the Arizona State Medical Society. In addition, I was given the help of the Veterans' Bureau facilities and Indian bureaus, and every particle of red tape was cut. Not only did the press of Arizona speak favorably

TABLE 2.—Ratio of Diabetes in the Population

Age	Males	Females
0-14.....	1:2,500	1:2,500
15-24.....	1:1,700	1:1,700
25-34.....	1:1,100	1:1,100
35-44.....	1:500	1:900
45-54.....	1:225	1:300
55-64.....	1:100	1:125
65 and over.....	1:70	1:50

These data, adapted from the National Health Survey, are based on 9,182 diabetic patients in a surveyed (urban) population of 2,502,391 persons.

of the study but their medical editor put in newspaper form the crude talks on diabetes which I had labored to devise and, finally, the pharmaceutical association of the state reduced the price of the solution used for the Benedict test for two months so that there would be no excuse for doctor or layman to be deprived of an examination of the urine. The Phoenix Pathological Laboratory reduced its fees for blood sugar tests to a wholesale minimum.

With all these agencies aiding and abetting the diabetic survey, I sent airmail letters to each doctor in

3. Royce, Josiah: Science 39: 551, 1914.

the state asking him if he would report by name or initial the diabetic patients under his care, and I confess also to the effrontery of asking him to tell me whether he himself had diabetes. The airmail letters were supplemented by two trips to Arizona and a three weeks stay in the state during which I traveled from Yuma to Ganado, from Douglas to Flagstaff; in fact, I visited all communities in the state with a population of more than 3,000 save two, and many of the smaller towns.

TABLE 3.—*Arizona and Rhode Island Populations per Square Mile and Crude and Adjusted Diabetic Mortalities, 1937 and 1930-1938*

1937	Popu- lation per Square Mile	Physi- cians to Popu- lation	Diabetic Mortality per 100,000			
			1937		1930-1938	
			Crude	Adjusted	Crude	Adjusted
Arizona.....	3.8	1:772	10.0	13	8.8	10.1
Rhode Island....	644.0	1:726	42.0	37	28.3	22.4

The doctors I met were extraordinarily kind. Often they welcomed me at dinner or at luncheon, perhaps in a hospital where I had an excellent opportunity to meet them individually, and when I wished to travel from one locality to another they would transmit me at a speed of 75 miles an hour, more or less, thus eliminating distance and taking advantage of Providence, R. I., with its speed limit of 25 miles an hour. Besides these more formal meetings I rang doorbells like any detail man and, when an elderly doctor was doubtful about his having or not having diabetes, got his specimen then and there.

In reporting the results of the canvass for diabetes in Arizona I will begin with that of small and special groups, because each yields its lesson. These groups are of especial value for comparison with similar ones elsewhere. The first is a microcosm.

Jews.—In Arizona Jews number about 2,000 (1,755 in 1937). They constitute less than one two-hundredth of the population, but when I counted Jews among all the diabetic patients reported by the doctors of the state they numbered eighteen, or about one fortieth of the total number of diabetic patients, or proportionately four or five times as many. Thus the Jewish racial incidence in Arizona is even stronger than that in Boston, where years ago there were two and one-half diabetic Jews for one diabetic Gentile, a figure based on larger numbers and, in my opinion, nearer to the truth.⁴ If the 100,000 \pm Mexicans now in Arizona, representing one fourth of the total population, were replaced by Jews, who show four times the total diabetic morbidity incidence, the figure for diabetic morbidity in Arizona would just about double the incidence I got for the whole state.

I sense your criticism that the Jews, like so many others of Arizona's population, are newcomers and do not fairly represent the original population of Arizona, but to this I would answer that there is very little indigenous population in that state. At a dinner of twenty-three physicians in Tucson, when I asked how many of those present were born in the state not one hand was raised. However, I grant the validity of such objections. Indeed, the opportunity to meet them was one of the reasons which led me to select Arizona as a test state for diabetes, because it has some 40,000 to 50,000 original inhabitants, namely the Indians.

In this field work among the Indians not one particle of credit is due to me. All is due to the physicians

in the Indian service, who cooperated in every way possible. I cannot say enough for that service, and I know whereof I speak, because I visited Indian hospitals in Sacaton, Ganado, Fort Lewis, San Carlos and the Indian school and Indian hospital in Phoenix. By no means did I canvass all the Indians or go to all the reservations with their varied institutions, but I can say emphatically that I had most cordial responses from the Indian Bureau in Washington, its representatives in the West and individually from all the government agencies, and what I say of the Indian service I can say also of the assistance I received from the two United States Veteran Facility hospitals in Tucson and Fort Whipple. Moreover, I should also mention the cooperation of the members of the staffs of the various hospitals in mining centers, Bisbee, Jerome and Globe, who took the pains to make it possible for me to meet and question physicians living nearby, although not on their own staffs.

The high grade of medical care afforded Indians in Arizona by the United States government is not sufficiently known, even among the physicians of Arizona. I cannot praise it too strongly not only for what it is doing now but for what I know has been arranged for it to do in the immediate future.

Indians.—From Washington I learned that two Indians yearly (actually eleven Indians for the six years 1934 to 1939) were reported to have died with diabetes. In addition, among 6,331 admissions (90 \pm per cent Indians) between the years 1931 and 1936 to the Sage Memorial Hospital at Ganado,⁵ a private institution on the Navajo reservation, the existence of diabetes was demonstrated in one Indian. When the final count of the cards with the names of the diabetic Indians living in Arizona was made I had seventy-one, and the statistical conscience of the statistical department of the Metropolitan Life Insurance Company, which revised my data, forced me to add two more, allocating these to Indians from the total number of cases with nationality unclassified, thus making seventy-three in all.

It is not strange that so few diabetic Indians were admitted to the Sage Memorial Hospital. Their patients are young. Among 1,429 admissions during 1939, only seventy-five were past the age of 50. The age distribution is given in table 4.

The survey certainly did not include all the Indians in the state. I should think it doubtful that it included
